MECL INTEGRATED CIRCUITS

Prepared by
Technical Information Center

This book presents technical data for a broad line of MECL integrated circuits. Complete specifications for the individual circuits are provided in the form of data sheets. In addition, selector guides are included to simplify the task of choosing the best combination of circuits for optimum system architecture.

Motorola reserves the right to make changes without further notice to any products herein to improve reliability, function or design. Motorola does not assume any liability arising out of the application or use of any product or circuit described herein; neither does it convey any license under its patent rights nor the rights of others. Motorola products are not authorized for use as components in life support devices or systems intended for surgical implant into the body or intended to support or sustain life. Buyer agrees to notify Motorola of any such intended end use whereupon Motorola shall determine availability and suitability of its product or products for the use intended. GENERAL INFORMATION

SECTION 1 — HIGH-SPEED LOGIC

High speed logic is used whenever improved system performance would increase a product's market value. For a given system design, high-speed logic is the most direct way to improve system performance and emitter-coupled logic (ECL) is today's fastest form of digital logic. Emitter-coupled logic offers both the logic speed and logic features to meet the market demands for higher performance systems.

MECL PRODUCTS

Motorola introduced the original monolithic emitter-coupled logic family with MECL I (1962) and followed this with MECL II (1966). These two families are now obsolete and have given way to the MECL III (MC1600 series), MECL 10K, PLL (MC12000 series) and the new MECL 10KH families.

Chronologically the third family introduced, MECL III (1968) is a higher power, higher speed logic. Typical 1 ns edge speeds and propagation delays along with greater than 500 MHz flip-flop toggle rates, make MECL III useful for high-speed test and communications equipment. Also, this family is used in the high-speed sections and critical timing delays of larger systems. For more general purpose applications, however, trends in large high-speed systems showed the need for an easy-to-use logic family with propagation delays on the order of 2 ns. To

match this requirement, the MECL 10,000 Series was introduced in 1971.

An important feature of MECL 10K is its compatibility with MECL III to facilitate using both families in the same system. A second important feature is its significant power economy — MECL 10K gates use less than one-half the power of MECL III.

Motorola introduced the MECL 10KH product family in 1981. This latest MECL family features 100% improvements in propagation delay and clock speeds while maintaining power supply currents equal to MECL 10K. MECL 10KH is voltage compensated allowing guaranteed dc and switching parameters over a $\pm 5\%$ power supply range. Noise margins have been improved by 75% over the MECL 10K series.

Compatibility with MECL 10K and MECL III is a key element in allowing users to enhance existing systems by increasing the speed in critical timing areas. Also, many MECL 10KH devices are pin out/functional duplications of the MECL 10K series devices. The emphasis of this new family will be placed on more powerful logic functions having more complexity and greater performance. With 1.0 ns propagation delays and 25 mW per gate, MECL 10KH features the best speed-power product of any ECL logic family available today.

MECL FAMILY COMPARISONS

Feature	MECL 10KH	MECL 10K		MECL III
		10,100 Series	10,200 Series	
1. Gate Propagation Delay	1.0 ns	2.0 ns	1.5 ns	1.0 ns
2. Output Edge Speed*	1.0 ns	3.5 ns	2.5 ns	1.0 ns
3. Flip-Flop Toggle Speed	250 MHz min	125 MHz min	200 MHz min	300–500 MHz min
4. Gate Power	25 mW	25 mW	25 mW	60 mW
5. Speed Power Product	25 pJ	50 pJ	37 pJ	60 pJ

*Output edge speed: MECL 10K/10KH measured 20% to 80%, MECL III measured 10% to 90% of E out.

Ambient Temperature Range	MECL 10KH	MECL 10K	MECL III	PLL
0° to 75°C	MC10H100 Series			MC12000 Series
–30°C to +85°C		MC10100 Series MC10200 Series	MC1600 Series	MC12000 Series

FIGURE 1b — OPERATING TEMPERATURE RANGE

MECL IN PERSPECTIVE

In evaluating any logic line, speed and power requirements are the obvious primary considerations. Figure 1 provides the basic parameters of the MECL 10KH, MECL 10K, and MECL III families. But these provide only the start of any comparative analysis, as there are a number of other important features that make MECL highly desirable for system implementation. Among these:

Complementary Outputs cause a function and its complement to appear simultaneously at the device outputs, without the use of external inverters. It reduces package count by eliminating the need for associated invert functions and, at the same time, cuts system power requirements and reduces timing differential problems arising from the time delays introduced by inverters.

High Input Impedance and Low Output Impedance permit large fan out and versatile drive characteristics.

Insignificant Power Supply Noise Generation, due to differential amplifier design which eliminates current spikes even during signal transition period.

Nearly Constant Power Supply Current Drain simplifies power-supply design and reduces costs.

Low Cross-Talk due to low-current switching in signal path and small (typically 850 mV) voltage swing, and to relatively long rise and fall times.

Wide Variety of Functions, including complex functions facilitated by low power dissipation (particularly in MECL 10KH and MECL 10K series). A basic MECL 10K gate consumes less than 8 mW in on-chip power in some complex functions.

Wide Performance Flexibility due to differential amplifier design which permits MECL circuits to be used as linear as well as digital circuits.

Transmission Line Drive Capability is afforded by the open emitter outputs of MECL devices. No "Line Drivers" are listed in MECL families, because every device is a line driver.

Wire-ORing reduces the number of logic devices required in a design by producing additional OR gate functions with only an interconnection.

Twisted Pair Drive Capability permits MECL circuits to drive twisted-pair transmission lines as long as 1000 feet.

Wire-Wrap Capability is possible with the MECL 10K family because of the slow rise and fall time characteristic of the circuits.

Open Emitter-Follower Outputs are used for MECL outputs to simplify signal line drive. The outputs match any line impedance and the absence of internal pulldown resistors saves power.

Input Pulldown Resistors of approximately 50 k Ω permit unused inputs to remain unconnected for easier circuit board layout.

MECL APPLICATIONS

Motorola's MECL product lines are designed for a wide range of systems needs. Within the computer market, MECL 10K is used in systems ranging from special purpose peripheral controllers to large mainframe computers. Big growth areas in this market include disk and communication channel controllers for larger systems and high performance minicomputers.

The industrial market primarily uses MECL for high performance test systems such as IC or PC board testers.

However, the high bandwidths of MECL 10KH, MECL 10K, MECL III, and MC12,000 are required for many frequency synthesizer systems using high speed phase lock loop networks. MECL will continue to grow in the industrial market through complex medical electronic products and high performance process control systems.

MECL 10K and MECL III have been accepted within the Federal market for numerous signal processors and navigation systems. Full military temperature range MECL 10K is offered in the MC10500 and MC10600 Series, and in the PLL family as the MC12500 Series.

BASIC CONSIDERATIONS FOR HIGH-SPEED LOGIC DESIGN

High-speed operation involves only four considerations that differ significantly from operation at low and medium speeds:

1. Time delays through interconnect wiring, which may have been ignored in medium-speed systems, become highly important at state-of-the-art speeds.

2. The possibility of distorted waveforms due to reflections on signal lines increases with edge speed.

3. The possibility of "crosstalk" between adjacent signal leads is proportionately increased in high-speed systems.

4. Electrical noise generation and pick-up are more detrimental at higher speeds.

In general, these four characteristics are speed- and frequency-dependent, and are virtually independent of the type of logic employed. The merit of a particular logic family is measured by how well it compensates for these deleterious effects in system applications.

The interconnect-wiring time delays can be reduced only by reducing the length of the interconnecting lines. At logic speeds of two nanoseconds, an equivalent "gate delay" is introduced by every foot of interconnecting wiring. Obviously, for functions interconnected within a single monolithic chip, the time delays of signals travelling from one function to another are insignificant. But for a great many externally interconnected parts, this can soon add up to an appreciable delay time. Hence, the greater the number of functions per chip, the higher the system speed. *MECL circuits, particularly those of the MECL 10K and MECL 10KH Series are designed with a propensity toward complex functions to enhance overall system speed.*

Waveform distortion due to line reflections also becomes troublesome principally at state-of-the-art speeds. At slow and medium speeds, reflections on interconnecting lines are not usually a serious problem. At higher speeds, however, line lengths can approach the wavelength of the signal and improperly terminated lines can result in reflections that will cause false triggering (see Figure 2). The solution, as in RF technology, is to employ "transmission-line" practices and properly terminate each signal line with its characteristic impedance at the end of its run. *The low-impedance, emitter-follower outputs of MECL circuits facilitate transmission-line practices without upsetting the voltage levels of the system.*

The increased affinity for crosstalk in high-speed circuits is the result of very steep leading and trailing edges (fast rise and fall times) of the high-speed signal. These steep wavefronts are rich in harmonics that couple readily to adjacent circuits. *In the design of MECL 10K and*

MECL 10KH, the rise and fall times have been deliberately slowed. This reduces the affinity for crosstalk without compromising other important performance parameters.

From the above, it is evident that the MECL logic line is not simply capable of operating at high speed, but has been specifically designed to reduce the problems that are normally associated with high-speed operation.

CIRCUIT DESCRIPTION

The typical MECL 10K circuit, Figure 3, consists of a differential-amplifier input circuit, a temperature and voltage compensated bias network, and emitter-follower outputs to restore dc levels and provide buffering for transmission line driving. High fan-out operation is possible be-

FIGURE 2a — UNTERMINATED TRANSMISSION LINE
(No Ground Plane Used)

FIGURE 2b — PROPERLY TERMINATED TRANSMISSION LINE
(Ground Plane Added)

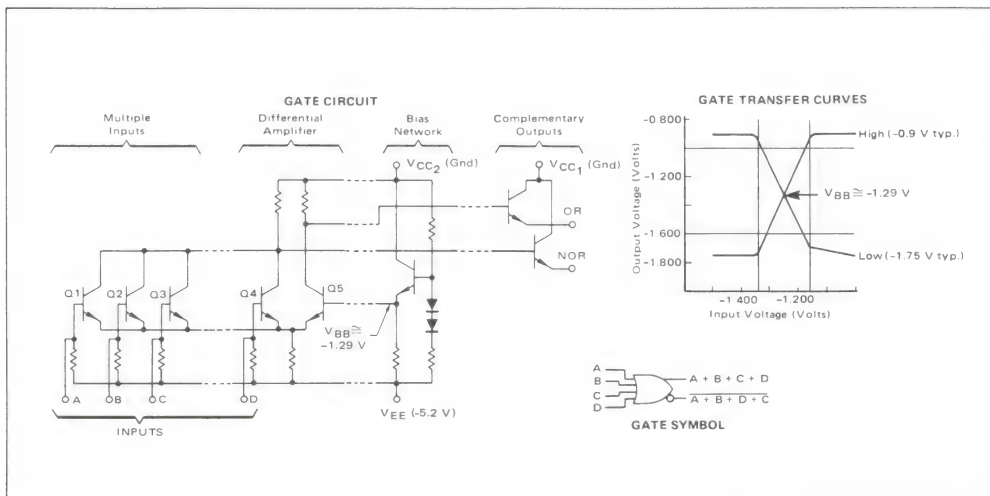

FIGURE 3 — MECL 10K GATE STRUCTURE AND SWITCHING BEHAVIOR

cause of the high input impedance of the differential amplifier input and the low output impedance of the emitter follower outputs. Power-supply noise is virtually eliminated by the nearly constant current drain of the differential amplifier, even during the transition period. Basic gate design provides for simultaneous output of both the OR function and its complement, the NOR function. The design of the MECL 10KH gate is unchanged, with two exceptions. The bias network has been replaced with a voltage regulator, and the differential amplifier source resistor has been replaced with a constant current source. (See section 2 for additional MECL 10KH information.)

Power-Supply Connections — Any of the power supply levels, V_{TT} , V_{CC} , or V_{EE} may be used as ground; however, the use of the V_{CC} node as ground results in best noise immunity. In such a case: $V_{CC} = 0$, $V_{TT} = -2.0$ V, $V_{EE} = -5.2$ V.

System Logic Specifications — The output logic swing of 0.85 V, as shown by the typical transfer characteristics curve, varies from a LOW state of $V_{OL} = -1.75$ V to a HIGH state of $V_{OH} = -0.9$ V with respect to ground.

Positive logic is used when reference is made to logical "0's" or "1's." Then

$$\begin{aligned} "0" &= -1.75 \text{ V} = \text{LOW} \\ "1" &= -0.9 \text{ V} = \text{HIGH} \end{aligned} \quad \text{typical}$$

Circuit Operation — Beginning with all logic inputs LOW (nominal -1.75 V), assume that Q1 through Q4 are cut off because their P-N base-emitter junctions are not

conducting, and the forward-biased Q5 is conducting. Under these conditions, with the base of Q5 held at -1.29 V by the V_{BB} network, its emitter will be one diode drop (0.8 V) more negative than its base, or -2.09 V. (The 0.8 V differential is a characteristic of this P-N junction.) The base-to-emitter differential across Q1 — Q4 is then the difference between the common emitter voltage (-2.09 V) and the LOW logic level (-1.75 V) or 0.34 V. This is less than the threshold voltage of Q1 through Q4 so that these transistors will remain cut off.

When any one (or all) of the logic inputs are shifted upward from the -1.75 V LOW state to the -0.9 V HIGH state, the base voltage of that transistor increases beyond the threshold point and the transistor turns on. When this happens, the voltage at the common-emitter point rises from -2.09 V to -1.7 (one diode drop below the -0.9 V base voltage of the input transistor), and since the base voltage of the fixed-bias transistor (Q5) is held at -1.29 V, the base-emitter voltage Q5 cannot sustain conduction. Hence, this transistor is cut off.

This action is reversible, so that when the input signal(s) return to the LOW state, Q1 — Q4 are again turned off and Q5 again becomes forward biased. The collector voltages resulting from the switching action of Q1 — Q4 and Q5 are transferred through the output emitter-follower to the output terminal. Note that the differential action of the switching transistors (one section being off when the other is on) furnishes simultaneous complementary signals at the output. This action also maintains constant power supply current drain.

DEFINITIONS OF LETTER SYMBOLS AND ABBREVIATIONS

Current:

I_{CC}	Total power supply current drawn from the positive supply by a MECL unit under test.
I_{CBO}	Leakage current from input transistor on MECL devices without pulldown resistors when test voltage is applied.
I_{CCH}	Current drain from V_{CC} power supply with all inputs at logic HIGH level.
I_{CCL}	Current drain from V_{CC} power supply with all inputs at logic LOW level.
I_E	Total power supply current drawn from a MECL test unit by the negative power supply.
I_F	Forward diode current drawn from an input of a saturated logic-to-MECL translator when that input is at ground potential.
I_{in}	Current into the input of the test unit when a maximum logic HIGH ($V_{IH \text{ max}}$) is applied at that input.
I_{INH}	HIGH level input current into a node with a specified HIGH level ($V_{IH \text{ max}}$) logic voltage applied to that node. (Same as I_{in} for positive logic.)
I_{INL}	LOW level input current, into a node with a specified LOW level ($V_{IL \text{ min}}$) logic voltage applied to that node.
I_L	Load current that is drawn from a MECL circuit output when measuring the output HIGH level voltage.

I_{OH}	HIGH level output current: the current flowing into the output, at a specified HIGH level output voltage.
I_{OL}	LOW level output current: the current flowing into the output, at a specified LOW level output voltage.
I_{OS}	Output short circuit current.
I_{out}	Output current (from a device or circuit, under such conditions mentioned in context).
I_R	Reverse current drawn from a transistor input of a test unit when V_{EE} is applied at that input.
I_{SC}	Short-circuit current drawn from a translator saturating output when that output is at ground potential.

Voltage:

V_{BB}	Reference bias supply voltage.
V_{BE}	Base-to-emitter voltage drop of a transistor at specified collector and base currents.
V_{CB}	Collector-to-base voltage drop of a transistor at specified collector and base currents.
V_{CC}	General term for the most positive power supply voltage to a MECL device (usually ground, except for translator and interface circuits).
V_{CC1}	Most positive power supply voltage (output devices). (Usually ground for MECL devices.)

Voltage (cont.):

V_{CC2}	Most positive power supply voltage (current switches and bias driver). (Usually ground for MECL devices.)
V_{EE}	Most negative power supply voltage for a circuit (usually -5.2 V for MECL devices).
V_F	Input voltage for measuring I_F on TTL interface circuits.
V_{IH}	Input logic HIGH voltage level (nominal value).
$V_{IH\ max}$	Maximum HIGH level input voltage: The most positive (least negative) value of high-level input voltage, for which operation of the logic element within specification limits is guaranteed.
V_{IHA}	Input logic HIGH threshold voltage level.
$V_{IHA\ min}$	Minimum input logic HIGH level (threshold) voltage for which performance is specified.
$V_{IH\ min}$	Minimum HIGH level input voltage: The least positive (most negative) value of HIGH level input voltage for which operation of the logic element within specification limits is guaranteed.
V_{IL}	Input logic LOW voltage level (nominal value).
$V_{IL\ max}$	Maximum LOW level input voltage: The most positive (least negative) value of LOW level input voltage for which operation of the logic element within specification limits is guaranteed.
V_{ILA}	Input logic LOW threshold voltage level.
$V_{ILA\ max}$	Maximum input logic LOW level (threshold) voltage for which performance is specified.
$V_{IL\ min}$	Minimum LOW level input voltage: The least positive (most negative) value of LOW level input voltage for which operation of the logic element within specification limits is guaranteed.
V_{in}	Input voltage (to a circuit or device).
V_{max}	Maximum (most positive) supply voltage, permitted under a specified set of conditions.
V_{OH}	Output logic HIGH voltage level: The voltage level at an output terminal for a specified output current, with the specified conditions applied to establish a HIGH level at the output.
V_{OHA}	Output logic HIGH threshold voltage level.
$V_{OHA\ min}$	Minimum output HIGH threshold voltage level for which performance is specified.
$V_{OH\ max}$	Maximum output HIGH or high-level voltage for given inputs.
$V_{OH\ min}$	Minimum output HIGH or high-level voltage for given inputs.
V_{OL}	Output logic LOW voltage level: The voltage level at the output terminal for a specified output current, with the specified conditions applied to establish a LOW level at the output.
V_{OLA}	Output logic LOW threshold voltage level.
$V_{OLA\ max}$	Maximum output LOW threshold voltage level for which performance is specified.

$V_{OL\ max}$	Maximum output LOW level voltage for given inputs.
$V_{OL\ min}$	Minimum output LOW level voltage for given inputs.
V_{TT}	Line load-resistor terminating voltage for outputs from a MECL device.
V_{OLS1}	Output logic LOW level on MECL 10,000 line receiver devices with all inputs at V_{EE} voltage level.
V_{OLS2}	Output logic LOW level on MECL 10,000 line receiver devices with all inputs open.

Time Parameters:

t_+	Waveform rise time (LOW to HIGH), 10% to 90%, or 20% to 80%, as specified.
t_-	Waveform fall time (HIGH to LOW), 90% to 10%, or 80% to 20%, as specified.
t_r	Same as t_+
t_f	Same as t_-
$t_{+ -}$	Propagation Delay, see Figure 9.
$t_{- +}$	Propagation Delay, see Figure 9.
t_{pd}	Propagation delay, input to output from the 50% point of the input waveform at pin x (falling edge noted by $-$ or rising edge noted by $+$) to the 50% point of the output waveform at pin y (falling edge noted by $-$ or rising edge noted by $+$). (Cf Figure 9.)
$t_{x \pm y \pm}$	
t_{x+}	Output waveform rise time as measured from 10% to 90% or 20% to 80% points on waveform (whichever is specified) at pin x with input conditions as specified.
t_{x-}	Output waveform fall time as measured from 90% to 10% or 80% to 20% points on waveform (whichever is specified) at pin x , with input conditions as specified.
f_{Tog}	Toggle frequency of a flip-flop or counter device.
f_{shift}	Shift rate for a shift register.

Read Mode (Memories)

t_{ACS}	Chip Select Access Time
t_{RCS}	Chip Select Recovery Time
t_{AA}	Address Access Time

Write Mode (Memories)

t_W	Write Pulse Width
t_{WSD}	Data Setup Time Prior to Write
t_{WHD}	Data Hold Time After Write
t_{WSA}	Address setup time prior to write
t_{WHA}	Address hold time after write
t_{WSCS}	Chip select setup time prior to write
t_{WHCS}	Chip select hold time after write
t_{WS}	Write disable time
t_{WR}	Write recovery time

Temperature:

T_{stg}	Maximum temperature at which device may be stored without damage or performance degradation.
T_J	Junction (or die) temperature of an integrated circuit device.
T_A	Ambient (environment) temperature existing in the immediate vicinity of an integrated circuit device package.
θ_{JA}	Thermal resistance of an IC package, junction to ambient.
θ_{JC}	Thermal resistance of an IC package, junction to case.
lfpm	Linear feet per minute.
θ_{CA}	Thermal resistance of an IC package, case to ambient.

Miscellaneous:

e_g	Signal generator inputs to a test circuit.
TP_{in}	Test point at input of unit under test.
TP_{out}	Test point at output of unit under test.
D.U.T.	Device under test.
C_{in}	Input capacitance.
C_{out}	Output capacitance.
Z_{out}	Output impedance.
P_D	The total dc power applied to a device, not including any power delivered from the device to a load.
R_L	Load Resistance.
R_T	Terminating (load) resistor.
R_p	An input pull-down resistor (i.e., connected to the most negative voltage).
P.U.T.	Pin under test.

MECL POSITIVE AND NEGATIVE LOGIC

INTRODUCTION

The increasing popularity and use of emitter coupled logic has created a dilemma for some logic designers. Saturated logic families such as TTL have traditionally been designed with the NAND function as the basic logic function, however, the basic ECL logic function is the NOR function (positive logic). Therefore, the designer may either design ECL systems with positive logic using the

NOR, or design with negative logic using the NAND. Which is the more convenient? On the one hand the designer is familiar with positive logic levels and definitions, and on the other hand, he is familiar with implementing systems using NAND functions. Perhaps a presentation of the basic definitions and characteristics of positive and negative logic will clarify the situation and eliminate misunderstanding.

FIGURE 1 — Basic MECL Gate Circuit and Logic Function
In Positive and Negative Nomenclature.

Circuit diagrams external to Motorola products are included as a means of illustrating typical semiconductor applications; consequently, complete information sufficient for construction purposes is not necessarily given. The information in this Application Note has been carefully checked and is believed to be entirely reliable. However, no responsibility is assumed for inaccuracies. Furthermore, such information does not convey to the purchaser of the semiconductor devices described any license under the patent rights of Motorola Inc. or others.

LOGIC EQUIVALENCES

Binary logic must have two states to represent the binary 1 and 0. With ECL the typical states are a high level of -0.9 volts and a low level of -1.7 volts. Two choices are possible then to represent the binary 1 and 0. Positive logic defines the 1 or "true" state as the most positive voltage level, whereas negative logic defines the most negative voltage level as the 1 or "true" state. Because of the difference in definition of states, the basic ECL gate is a NOR function in positive logic and is a NAND function in negative logic.

Figure 1 more clearly shows the above comparison of functions. Table 1 lists the output voltage level as a function of input voltage levels of the MECL gate circuit shown. Table 2 translates the voltage levels into the

appropriate negative logic levels which show the function to be $C = \overline{A \cdot B}$; that is, the circuit performs the NAND function. Table 3 translates the equivalent positive logic function into $C = A + B$, the NOR function.

Similar comparisons can be made for other positive logic functions. As an example, the positive OR function translates to the negative AND function. Figure 2 shows a comparison of several common logic functions.

Any function available in a logic family may be expressed in terms of positive or negative logic, bearing in mind the definition of logic levels. The choice of logic definition, as previously stated, is dependent on the designer. Motorola provides both positive and negative logic symbols on data sheets for the popular MECL 10,000 logic series.

SUMMARY

Conversion from one logic form to another or the use of a particular logic form need not be a complicated process. If the designer uses the logic form with which he is familiar and bears in mind the previously mentioned definition of levels, problems arising from definition of logic functions should be minimized.

SECTION II — TECHNICAL DATA

GENERAL CHARACTERISTICS AND SPECIFICATIONS

(See pages 1-5 through 1-7 for definitions of symbols and abbreviations.)

In subsequent sections of this Data Book, the important MECL parameters are identified and characterized, and complete data provided for each of the functions. To make this data as useful as possible, and to avoid a great deal of repetition, the data that is common to all functional blocks in a line is not repeated on each individual sheet. Rather, these common characteristics, as well as the application information that applies to each family, are discussed in this section.

In general, the common characteristics of major importance are:

Maximum Ratings, including both dc and ac characteristics and temperature limits;

Transfer Characteristics, which define logic levels and switching thresholds;

DC Parameters, such as output levels, threshold levels, and forcing functions.

AC Parameters, such as propagation delays, rise and fall times and other time dependent characteristics.

In addition, this section will discuss general layout and design guides that will help the designer in building and testing systems with MECL circuits.

LETTER SYMBOLS AND ABBREVIATIONS

Throughout this section, and in the subsequent data sheets, letter symbols and abbreviations will be used in discussing electrical characteristics and specifications. The symbols used in this book, and their definitions, are listed on the preceding pages.

MAXIMUM RATINGS

The limit parameters beyond which the life of the devices may be impaired are given in Figure 4a. In addition, Table 4b provides certain limits which, if exceeded, will not damage the devices, but could degrade the performance below that of the guaranteed specifications.

FIGURE 4a — LIMITS BEYOND WHICH DEVICE LIFE MAY BE IMPAIRED

Characteristic	Symbol	Unit	MECL 10KH	MECL 10K	MECL III
Power Supply	V_{EE}	Vdc	-8.0 to 0	-8.0 to 0	-8.0 to 0
Input Voltage ($V_{CC} = 0$)	V_{in}	Vdc	0 to V_{EE}	0 to V_{EE}	0 to V_{EE}
Output Source Current Continuous	I_{out}	mA _{dc}	50	50	40
Output Source Current Surge	I_{out}	mA _{dc}	100	100	—
Storage Temperature	T_{stg}	°C	-65 to +150	-65 to +150	-65 to +150
Junction Temperature Ceramic Package①	T_J	°C	165	165	165②
Junction Temperature Plastic Package③	T_J	°C	140	140	140

NOTES: 1. Maximum T_J may be exceeded ($\leq 250^\circ\text{C}$) for short periods of time (≤ 240 hours) without significant reduction in device life.

2. Except MC1670 which has a maximum junction temperature = 145°C .

3. For long term (≥ 10 yrs.) max T_J of 110°C required. Max T_J may be exceeded ($\leq 175^\circ\text{C}$) for short periods of time (≤ 240 hours) without significant reduction in device life.

NOTES: 1. With airflow ≥ 500 lfm.

2. Functionality only. Data sheet limits are specified for $-5.2 \text{ V} \pm 0.010 \text{ V}$.

3. Except MC1648 which has an internal output pulldown resistor.

4. Functional and Data sheet limits.

FIGURE 5 — MECL TRANSFER CURVES
and SPECIFICATION TEST POINTS

MECL TRANSFER CURVES

For MECL logic gates, the dual (complementary) outputs must be represented by two transfer curves: one to describe the OR switching action and one to describe the NOR switching action. Typical transfer curves and associated data for the MECL 10K/10KH family are shown in Figures 5a and 5b respectively.

It is not necessary to measure transfer curves at all points of the curves. To guarantee correct operation it is sufficient merely to measure two sets of min/max logic level parameters.

The first set is obtained for 10K by applying test voltages, $V_{IL \min}$ and $V_{IH \max}$ (sequentially) to the gate inputs, and measuring the OR and NOR output levels to make sure they are between $V_{OL \max}$ and $V_{OL \min}$, and $V_{OH \max}$ and $V_{OH \min}$ specifications.

The second set of logic level parameters relates to the switching thresholds. This set of data is distinguished by an "A" in symbol subscripts. A test voltage, $V_{ILA \max}$, is applied to the gate and the NOR and OR outputs are measured to see that they are above the $V_{OHA \min}$ and below the $V_{OLA \max}$ levels, respectively. Similar checks are made using the test input voltage $V_{IHA \min}$.

The result of these specifications insures that:

- The switching threshold ($\approx V_{BB}$) falls within the darkest rectangle; i.e. switching does not begin outside this rectangle;
- Quiescent logic levels fall in the lightest shaded ranges;
- Guaranteed noise immunity is met.

As shown in Figure 6, MECL 10K outputs rise with increasing ambient temperature. All circuits in each fam-

ily have the same worst-case output level specifications regardless of power dissipation or junction temperature differences to reduce loss of noise margin due to thermal differences.

All of these specifications assume -5.2 V power supply operation. Operation at other power-supply voltages is possible, but will result in further transfer curve changes. Figure 7 gives rate of change of output voltages as a function of power supply.

FIGURE 6 — TYPICAL TRANSFER
CHARACTERISTICS AS A FUNCTION
OF TEMPERATURE (MECL 10K)

FIGURE 7 — TYPICAL LEVEL CHANGE RATES

Voltage	MECL 10KH	MECL 10K	MECL III
$\Delta V_{OH} / \Delta V_{EE}$	0.008	0.016	0.033
$\Delta V_{OL} / \Delta V_{EE}$	0.020	0.250	0.270
$\Delta V_{BB} / \Delta V_{EE}$	0.010	0.148	0.140

NOISE MARGIN

"Noise margin" is a measure of logic circuit's resistance to undesired switching. MECL noise margin is defined in terms of the specification points surrounding the switching threshold. The critical parameters of interest here are those designated with the "A" subscript ($V_{OHA\ min}$, $V_{OLA\ max}$, $V_{IHA\ min}$, $V_{ILA\ max}$) in the transfer characteristic curves. MECL 10KH is specified and tested with $V_{OHA\ min}$ equal $V_{OH\ min}$, $V_{OLA\ max}$ equal $V_{OL\ max}$, $V_{IHA\ min}$ equal $V_{IH\ min}$ and $V_{ILA\ max}$ equal $V_{IL\ max}$. Guaranteed noise margin (NM) is defined as follows:

$$NM_{HIGH\ LEVEL} = V_{OHA\ min} - V_{IHA\ min}$$

$$NM_{LOW\ LEVEL} = V_{ILA\ max} - V_{OLA\ max}$$

To see how noise margin is computed, assume a MECL gate drives a similar MECL gate, Figure 8.

At a gate input (point B) equal to $V_{ILA\ max}$, MECL gate #2 can begin to enter the shaded transition region.

This is a "worst case" condition, since the $V_{OLA\ max}$ specification point guarantees that no device can enter the transition region before an input equal to $V_{ILA\ max}$ is reached. Clearly then, $V_{ILA\ max}$ is one critical point for noise margin computation, since it is the edge of the transition region.

To find the other critical voltage, consider the output from MECL gate #1 (point A). What is the most positive value possible for this voltage (considering worst case specifications)? From Figure 8 it can be observed that the $V_{OLA\ max}$ specification insures that the LOW state OR output from gate #1 can be no greater than $V_{OLA\ max}$.

Note that $V_{OLA\ max}$ is more negative than $V_{ILA\ max}$. Thus, with $V_{OLA\ max}$ at the input to gate #2, the transition region is not yet reached. (The input voltage to gate #2 is still to the left of $V_{ILA\ max}$ on the transfer curve.)

In order to ever run the chance of switching gate #2, we would need an additional voltage, to move the input

from $V_{OLA\ max}$ to $V_{ILA\ max}$. This constitutes the "safety factor" known as noise margin. It can be calculated as the magnitude of the difference between the two specification voltages, or for the MECL 10K levels shown:

$$\begin{aligned} NM_{LOW} &= V_{ILA\ max} - V_{OLA\ max} \\ &= -1.475\ V - (-1.630\ V) \\ &= 155\ mV. \end{aligned}$$

Similarly, for the HIGH state:

$$\begin{aligned} NM_{HIGH} &= V_{OHA\ min} - V_{IHA\ min} \\ &= -0.980\ V - (-1.105\ V) \\ &= 125\ mV \end{aligned}$$

Analogous results are obtained when considering the "NOR" transfer data.

Note that these noise margins are absolute worst case conditions. The lesser of the two noise margins is that for the HIGH state, 125 mV. This then, constitutes the guaranteed margin against signal undershoot, and power or thermal disturbances.

As shown in the table, typical noise margins are usually better than guaranteed — by about 75 mV. For MECL 10KH the "noise margin" is 150 mV for NM low and NM high. (See Section 3 for details.)

Noise margin is a dc specification that can be calculated, since it is defined by specification points tabulated on MECL data sheets. However, by itself, this specification does not give a complete picture regarding the noise immunity of a system built with a particular set of circuits. Overall system noise immunity involves not only noise-margin specifications, but also other circuit-related factors that determine how difficult it is to apply a noise signal of sufficient magnitude and duration to cause the circuit to propagate a false logic state. In general, then, noise immunity involves line impedances, circuit output impedances, and propagation delay in addition to noise-margin specifications. This subject to discussed in greater detail in the MECL System Design Handbook, HB205.

FIGURE 8 — MECL Noise Margin Data

Specification Points for Determining Noise Margin

Noise Margin Computations		
Family	Guaranteed Worst-Case dc Noise Margin (V)	Typical dc Noise Margin (V)
MECL 10KH	0.150	0.270
MECL 10K	0.125	0.210
MECL III	0.115	0.200

AC OR SWITCHING PARAMETERS

Time-dependent specifications are those that define the effects of the circuit on a specified input signal, as it travels through the circuit. They include the time delay involved in changing the output level from one logic state to another. In addition, they include the time required for the output of a circuit to respond to the input signal,

designated as propagation delay, MECL waveform and propagation delay terminologies are depicted in Figure 9. Specific rise, fall, and propagation delay times are given on the data sheet for each specific functional block, but like the transfer characteristics, ac parameters are temperature and voltage dependent. Typical variations for MECL 10K are given in the curves of Figure 10.

FIGURE 9 — TYPICAL LOGIC WAVEFORMS

FIGURE 10a — TYPICAL PROPAGATION DELAY t_- versus V_{EE} AND TEMPERATURE (MECL 10K)

FIGURE 10b — TYPICAL PROPAGATION DELAY t_{++} versus V_{EE} AND TEMPERATURE (MECL 10K)

FIGURE 10c — TYPICAL FALL TIME (90% to 10%) versus TEMPERATURE AND SUPPLY VOLTAGE (MECL 10K)

FIGURE 10d — TYPICAL RISE TIME (10% to 90%) versus TEMPERATURE AND SUPPLY VOLTAGE (MECL 10K)

SETUP AND HOLD TIMES

Setup and hold times are two ac parameters which can easily be confused unless clearly defined. For MECL logic devices, t_{setup} is the minimum time (50% – 50%) before the positive transition of the clock pulse (C) that information must be present at the Data input (D) to insure proper operation of the device. The t_{hold} is defined similarly as the minimum time after the positive transition of the clock pulse (C) that the information must remain unchanged at the Data input (D) to insure proper operation. Setup and hold waveforms for logic devices are shown in Figure 11.

FIGURE 11 — SETUP AND HOLD WAVEFORMS FOR MECL LOGIC DEVICES

TESTING MECL 10KH, MECL 10K AND MECL III

To obtain results correlating with Motorola circuit specifications certain test techniques must be used. A schematic of a typical gate test circuit is shown in Figure 12.

This test circuit is the standard ac test configuration for most MECL devices. (Exceptions are shown with the device specification.)

A solid ground plane is used in the test setup, and capacitors bypass V_{CC1} , V_{CC2} , and V_{EE} pins to ground. All power leads and signal leads are kept as short as possible.

The sampling scope interface runs directly to the 50-ohm inputs of Channel A and B via 50-ohm coaxial cable. Equal-length coaxial cables must be used between the test set and the A and B scope inputs. A 50-ohm coax cable such as RG58/U or RG188A/U, is recommended.

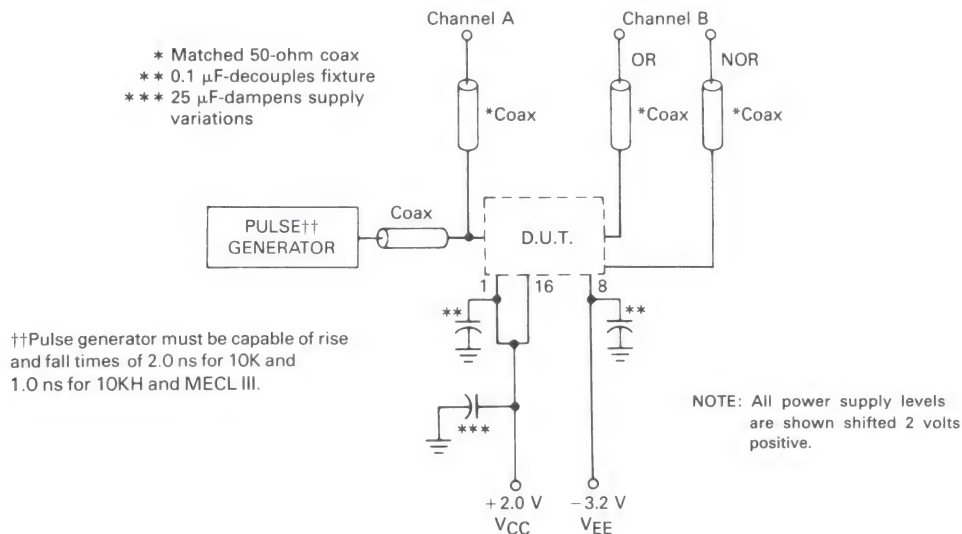

Interconnect fittings should be 50-ohm GR, BNC, Sealectro Conhex, or equivalent. Wire length should be $< 1/4$ inch from TP_{in} to input pin and TP_{out} to output pin.

The pulse generator must be capable of 2.0 ns rise and fall times for MECL 10K and 1.5 ns for MECL 10KH and MECL III. In addition, the generator voltage must have an offset to give MECL signal swings of $\approx \pm 400$ mV about a threshold of $\approx +0.7$ V when $V_{CC} = +2.0$ V and $V_{EE} = -3.2$ V for ac testing of logic devices.

The power supplies are shifted +2.0 V, so that the device under test has only one resistor value to load into the precision 50-ohm input impedance of the sampling oscilloscope. Use of this technique yields a close correlation between Motorola and customer testing. Unused outputs are loaded with a 50-ohm resistor (100-ohm for MC105XX devices) to ground. The positive supply (V_{CC}) should be decoupled from the test board by RF type 25 μ F capacitors to ground. The V_{CC} pins are bypassed to ground with 0.1 μ F, as is the V_{EE} pin.

Additional information on testing MECL 10K and understanding data sheets is found in Application Note AN701 and the MECL System Design Handbook, HB205.

FIGURE 12 — MECL LOGIC SWITCHING TIME TEST SETUP

SECTION III — OPERATIONAL DATA

POWER SUPPLY CONSIDERATIONS

MECL circuits are characterized with the V_{CC} point at ground potential and the V_{EE} point at -5.2 V. While this MECL convention is not necessarily mandatory, it does result in maximum noise immunity. This is so because any noise induced on the V_{EE} line is applied to the circuit as a common-mode signal which is rejected by the differential action of the MECL input circuit. Noise induced into the V_{CC} line is not cancelled out in this fashion. Hence, a good system ground at the V_{CC} bus is required for best noise immunity. Also, MECL 10KH circuits may be operated with V_{EE} at -4.5 V with a negligible loss of noise immunity.

Power supply regulation which will achieve 10% regulation or better at the device level is recommended. The -5.2 V power supply potential will result in best circuit speed. Other values for V_{EE} may be used. A more negative voltage will increase noise margins at a cost of increased power dissipation. A less negative voltage will have just the opposite effect. (Noise margins and performance specifications of MECL 10KH are unaffected by variations in V_{EE} because of the internal voltage regulation.)

On logic cards, a ground plane or ground bus system should be used. A bus system should be wide enough to prevent significant voltage drops between supply and device and to produce a low source inductance.

Although little power supply noise is generated by MECL logic, power supply bypass capacitors are recommended to handle switching currents caused by stray capacitance and asymmetric circuit loading. A parallel combination of a 1.0 μ F and a 100 pF capacitor at the power entrance to the board, and a 0.01 μ F low-inductance capacitor between ground and the -5.2 V line every four to six packages, are recommended.

Most MECL 10KH, MECL 10K and MECL III circuits have two V_{CC} leads. V_{CC1} supplies current to the output transistors and V_{CC2} is connected to the circuit logic transistors. The separate V_{CC} pins reduce cross-coupling between individual circuits within a package when the outputs are driving heavy loads. Circuits with large drive capability, similar to the MC10110, have two V_{CC1} pins. All V_{CC} pins should be connected to the ground plane or ground bus as close to the package as possible.

For further discussion of MECL power supply considerations to be made in system designing, see MECL System Design Handbook, HB205.

POWER DISSIPATION

The power dissipation of MECL functional blocks is specified on their respective data sheets. This specification does not include power dissipated in the output devices due to output termination. The omission of internal output pulldown resistors permits the use of external terminations designed to yield best system performance. To obtain total operating power dissipation of a particular functional block in a system, the dissipation of the output transistor, under load, must be added to the circuit power dissipation.

The table in Figure 13 lists the power dissipation in the output transistors plus that in the external terminating

resistors, for the more commonly used termination values and circuit configurations. To obtain true package power dissipation, one output-transistor power-dissipation value must be added to the specified package power dissipation for each external termination resistor used in conjunction with that package. To obtain system power dissipation, the stated dissipation in the external terminating resistors must be added as well. Unused outputs draw no power and may be ignored.

FIGURE 13 — AVERAGE POWER DISSIPATION IN OUTPUT CIRCUIT WITH EXTERNAL TERMINATING RESISTORS

Terminating Resistor Value	Output Transistor Power Dissipation (mW)	Terminating Resistor Power Dissipation (mW)
150 ohms to -2.0 Vdc	5.0	4.3
100 ohms to -2.0 Vdc	7.5	6.5
75 ohms to -2.0 Vdc	10	8.7
50 ohms to -2.0 Vdc	15	13
2.0 k ohms to V_{EE}	2.5	7.7
1.0 k ohm to V_{EE}	4.9	15.4
680 ohms to V_{EE}	7.2	22.6
510 ohms to V_{EE}	9.7	30.2
270 ohms to V_{EE}	18.3	57.2
82 ohms to V_{CC} and 130 ohms to V_{EE}	15	140

LOADING CHARACTERISTICS

The differential input to MECL circuits offers several advantages. Its common-mode-rejection feature offers immunity against power-supply noise injection, and its relatively high input impedance makes it possible for any circuit to drive a relatively large number of inputs without deterioration of the guaranteed noise margin. Hence, dc fanout with MECL circuits does not normally present a design problem.

Graphs showing typical output voltage levels as a function of load current for MECL 10KH, MECL 10K and MECL III shown in Figure 14. These graphs can be used to determine the actual output voltages for loads exceeding normal operation.

While dc loading causes a change in output voltage levels, thereby tending to affect noise margins, ac loading increases the capacitances associated with the circuit and, therefore, affects circuit speed, primarily rise and fall times.

MECL circuits typically have a 7 ohm output impedance and a relatively unaffected by capacitive loading on a positive-going output signal. However, the negative-going edge is dependent on the output pulldown or termination resistor. Loading close to a MECL output pin will cause an additional propagation delay of 0.1 ns per fanout load with a 50 ohm resistor to -2.0 Vdc or 270 ohms to -5.2 Vdc. A 100 ohm resistor to -2.0 Vdc or

510 ohms to -5.2 Vdc results in an additional 0.2 ns propagation delay per fanout load.

Terminated transmission line signal interconnections are used for best system performance. The propagation delay and rise time of a driving gate are affected very little by capacitance loading along a matched parallel-terminated transmission line. However, the delay and characteristic impedance of the transmission line itself are affected by the distributed capacitance. Signal propagation down the line will be increased by a factor, $\sqrt{1 + C_d/C_0}$. Here C_0 is the normal intrinsic line capaci-

tance, and C_d is the distributed capacitance due to loading and stubs off the line.

Maximum allowable stub lengths for loading off of a MECL 10K transmission line vary with the line impedance. For example, with $Z_0 = 50$ ohms, maximum stub length would be 4.5 inches (1.8 in. for MECL III). But when $Z_0 = 100$ ohms, the maximum allowable stub length is decreased to 2.8 inches (1.0 in. for MECL III).

The input loading capacitance of a MECL 10KH and MECL 10K gate is about 2.9 pF and 3.3 pF for MECL III. To allow for the IC connector or solder connection and a short stub length, 5 to 7 pF is commonly used in loading calculations.

**FIGURE 14 — OUTPUT VOLTAGE LEVELS
versus DC LOADING**

UNUSED MECL INPUTS

The input impedance of a differential amplifier, as used in the typical MECL input circuit, is very high when the applied signal level is low. Under low-signal conditions, therefore, any leakage to the input capacitance of the gate could cause a gradual buildup of voltage on the input lead, thereby adversely affecting the switching characteristics at low repetition rates.

All single-ended input MECL logic circuits contain input pulldown resistors between the input transistor bases and V_{EE} . As a result, unused inputs may be left unconnected (the resistor provides a sink for I_{CBO} leakage currents, and inputs are held sufficiently negative that circuits will not trigger due to noise coupled into such inputs). Input pulldown resistor values are typically 50 k Ω and are not to be used as pulldown resistors for preceding open-emitter outputs.

Some MECL devices do not have input pulldowns. Examples are the differential line receivers. If a single differential receiver within a package is unused, one input of that receiver must be tied to the V_{BB} pin provided, and the other input goes to V_{EE} or is left open.

MECL circuits do not operate properly when inputs are connected to V_{CC} for a HIGH logic level. Proper design practice is to set a HIGH level as about -0.9 volts below V_{CC} with a resistor divider, a diode drop, or an unused gate output.

SECTION IV — SYSTEM DESIGN CONSIDERATIONS

THERMAL MANAGEMENT

Circuit performance and long-term circuit reliability are affected by die temperature. Normally, both are improved by keeping the IC junction temperatures low.

Electrical power dissipated in any integrated circuit is a source of heat. This heat source increases the temperature of the die relative to some reference point, normally the ambient temperature of 25°C in still air. The temperature increase, then, depends on the amount of power dissipated in the circuit and on the net thermal resistance between the heat source and the reference point.

The temperature at the junction is a function of the packaging and mounting system's ability to remove heat generated in the circuit — from the junction region to the ambient environment. The basic formula (a) for converting power dissipation to estimated junction temperature is:

$$T_J = T_A + P_D(\bar{\theta}_{JC} + \bar{\theta}_{CA}) \quad (1)$$

or

$$T_J = T_A + P_D(\bar{\theta}_{JA}) \quad (2)$$

where

T_J = maximum junction temperature

T_A = maximum ambient temperature

P_D = calculated maximum power dissipation including effects of external loads (see Power Dissipation in section III).

$\bar{\theta}_{JC}$ = average thermal resistance, junction to case

$\bar{\theta}_{CA}$ = average thermal resistance, case to ambient

$\bar{\theta}_{JA}$ = average thermal resistance, junction to ambient

This Motorola recommended formula has been approved by RADC and DESC for calculating a "practical" maximum operating junction temperature for MIL-M-38510 (JAN) MECL 10K devices.

Only two terms on the right side of equation (1) can be varied by the user — the ambient temperature, and the device case-to-ambient thermal resistance, $\bar{\theta}_{CA}$. (To some extent the device power dissipation can be also controlled, but under recommended use the V_{EE} supply and loading dictate a fixed power dissipation.) Both system air flow and the package mounting technique affect the $\bar{\theta}_{CA}$ thermal resistance term. $\bar{\theta}_{JC}$ is essentially independent of air flow and external mounting method, but is sensitive to package material, die bonding method, and die area.

NOTES:

1. All plastic packages use copper lead frames — ceramic packages use alloy 42 frames.
2. Body style DIL is "Dual-In-Line."
3. Standard Mounting Methods:
 - a. Dual-In-Line In Socket or P/C board with no contact between bottom of package and socket or P/C board.
 - b. Flat Pack — Bottom of package in direct contact with non-metallized area of P/C board.
 - c. PLCC packages solder attached to traces on 2.24" x 2.24" x 0.062" FR4 type glass epoxy board with 1 oz./S.F. copper (solder coated) mounted to tester with 3 leads of 24 gauge copper wire.
4. Case Outline 649
5. Case Outline 623

For applications where the case is held at essentially a fixed temperature by mounting on a large or temperature-controlled heatsink, the estimated junction temperature is calculated by:

$$T_J = T_C + P_D (\bar{\theta}_{JC}) \quad (3)$$

where T_C = maximum case temperature and the other parameters are as previously defined.

The maximum and average thermal resistance values for standard MECL IC packages are given in Figure 15. In Figure 16, this basic data is converted into graphs showing the maximum power dissipation allowable at various ambient temperatures (still air) for circuits mounted in the different packages, taking into account the maximum permissible operating junction temperature for long term life ($\geq 100,000$ hours for ceramic packages).

AIR FLOW

The effect of air flow over the packages on $\bar{\theta}_{JA}$ (due to a decrease in $\bar{\theta}_{CA}$) is illustrated in the graphs of Figure 17. This air flow reduces the thermal resistance of the package, therefore permitting a corresponding increase in power dissipation without exceeding the maximum permissible operating junction temperature.

As an example of the use of the information above, the maximum junction temperature for a 16 lead ceramic dual-in-line packaged MECL 10K quad OR/NOR gate (MC10101L) loaded with four 50 ohm loads can be calculated. Maximum total power dissipation (including 4 output loads) for this quad gate is 195 mW. Assume for this thermal study that air flow is 500 linear feet per minute. From Figure 17, $\bar{\theta}_{JA}$ is 50°C/W . With T_A (air flow temperature at the device) equal to 25°C , the following maximum junction temperature results:

$$T_J = P_D (\bar{\theta}_{JA}) + T_A$$

$$T_J = (0.195 \text{ W}) (50^\circ\text{C/W} + 25^\circ\text{C} = 34.8^\circ\text{C})$$

Under the above operating conditions, the MECL 10K quad gate has its junction elevated above ambient temperature by only 9.8°C .

Even though different device types mounted on a printed circuit board may each have different power dissipations, all will have the same input and output levels provided that each is subject to identical air flow and the same ambient air temperature. This eases design, since the only change in levels between devices is due to the increase in ambient temperatures as the air passes over the devices, or differences in ambient temperature between two devices.

**FIGURE 18 — THERMAL GRADIENT OF JUNCTION
TEMPERATURE
(16-Pin MECL Dual-In-Line Package)**

Power Dissipation (mW)	Junction Temperature Gradient (°C/Package)
200	0.4
250	0.5
300	0.63
400	0.88

Devices mounted on 0.062" PC board with Z axis spacing of 0.5".
Air flow is 500 lfpm along the Z axis.

The majority of MECL 10KH, MECL 10K, and MECL III users employ some form of air-flow cooling. As air passes over each device on a printed circuit board, it absorbs heat from each package. This heat gradient from the first package to the last package is a function of the air flow rate and individual package dissipations. Figure 18 provides gradient data at power levels of 200 mW, 250 mW, 300 mW, and 400 mW with an air flow rate of 500 lfpm. These figures show the proportionate increase in the

**FIGURE 17C — AIRFLOW versus THERMAL RESISTANCE
(PLASTIC DUAL-IN-LINE PACKAGE)**

**FIGURE 17D — AIRFLOW versus THERMAL RESISTANCE
(PLCC PACKAGE)**

junction temperature of each dual-in-line package as the air passes over each device. For higher rates of air flow the change in junction temperature from package to package down the airstream will be lower due to greater cooling.

OPTIMIZING THE LONG TERM RELIABILITY OF PLASTIC PACKAGES

Today's plastic integrated circuit packages are as reliable as ceramic packages under most environmental conditions. However when the ultimate in system reliability is required, thermal management must be considered as a prime system design goal.

Modern plastic package assembly technology utilizes gold wire bonded to aluminum bonding pads throughout the electronics industry. When exposed to high temperatures for protracted periods of time an intermetallic compound can form in the bond area resulting in high impedance contacts and degradation of device performance. Since the formation of intermetallic compounds is directly related to device junction temperature, it is incumbent on the designer to determine that the device junction temperatures are consistent with system reliability goals.

Predicting Bond Failure Time:

Based on the results of almost ten (10) years of +125°C operating life testing, a special arrhenius equation has been developed to show the relationship between junction temperature and reliability.

$$(1) T = (6.376 \times 10^{-9}) e^{\left[\frac{11554.267}{273.15 + T_J} \right]}$$

Where: T = Time in hours to 0.1% bond failure (1 failure per 1,000 bonds).

T_J = Device junction temperature, °C.

And:

$$(2) T_J = T_A + P_D \theta_{JA} = T_A + \Delta T_J$$

Where: T_J = Device junction temperature, °C.

T_A = Ambient temperature, °C.

P_D = Device power dissipation in watts.

θ_{JA} = Device thermal resistance, junction to air, °C/Watt.

ΔT_J = Increase in junction temperature due to on-chip power dissipation.

Table 1 shows the relationship between junction temperature, and continuous operating time to 0.1% bond failure, (1 failure per 1,000 bonds).

TABLE 4 — DEVICE JUNCTION TEMPERATURE versus TIME TO 0.1% BOND FAILURES.

Junction Temperature °C	Time, Hours	Time, Years
80	1,032,200	117.8
90	419,300	47.9
100	178,700	20.4
110	79,600	9.4
120	37,000	4.2
130	17,800	2.0
140	8,900	1.0

Table 4 is graphically illustrated in Figure 19 which shows that the reliability for plastic and ceramic devices are the same until elevated junction temperatures induces intermetallic failures in plastic devices. Early and mid-life failure rates of plastic devices are not effected by this intermetallic mechanism.

FIGURE 19. FAILURE RATE versus TIME JUNCTION TEMPERATURE

MECL Junction Temperatures:

Power levels have been calculated for a number of MECL 10K and MECL 10KH devices in 20 pin plastic leaded chip carriers and translated to the resulting increase of junction temperature (ΔT_J) for still air and moving air at 500 LFPM using equation 2 and are shown in Table 5.

NOTES:

- (1) All ECL outputs are loaded with a 50 Ω resistor and assumed operating at 50% duty cycle.
- (2) ΔT_J for ECL to TTL translators are excluded since the supply current to the TTL section is dependent on frequency, duty cycle and loading.
- (3) Thermal Resistance (θ_{JA}) measured with PLCC packages solder attached to traces on 2.24" x 2.24" x 0.062" FR4 type glass epoxy board with 1 oz./sq. ft. copper (solder-coated) mounted to tester with 3 leads of 24 gauge copper wire.
- (4) 28 lead PLCC.

Case Example:

After the desired system failure rate has been established for failure mechanisms other than intermetallics, each plastic device in the system should be evaluated for maximum junction temperature using Table 5. Knowing the maximum junction temperature refer to Table 4 or Equation 1 to determine the continuous operating time required to 0.1% bond failures due to intermetallic formation. At this time, system reliability departs from the desired value as indicated in Figure 19.

To illustrate, assume that system ambient air temperature is 55°C (an accepted industry standard for evaluating system failure rates). Reference is made to Table 5 to determine the maximum junction temperature for each device for still air and transverse air flow of 500 LFPM.

Adding the 55°C ambient to the highest ΔT_J listed, 77.8°C (for the MC10H334 with no air flow), gives a maximum junction temperature of 132.8°C. Reference to Table 4 indicates a departure from the desired failure rate after about 2 years of constant exposure to this junction temperature. If 500 LFPM of air flow is utilized, maximum junction temperature for this device is reduced to 104.3°C for which Table 4 indicates an increased failure rate in about 15 years.

Air flow is one method of thermal management which should be considered for system longevity. Other commonly used methods include heat sinks for higher powered devices, refrigerated air flow and lower density board stuffing.

The material presented here emphasizes the need to consider thermal management as an integral part of system design and also the tools to determine if the management methods being considered are adequate to produce the desired system reliability.

THERMAL EFFECTS ON NOISE MARGIN

The data sheet dc specifications for standard MECL 10K and MECL III devices are given for an operating temperature range from -30°C to +85°C (0° to +75°C for MECL 10KH and memories). These values are based on having an airflow of 500 lfpm over socket or P/C board mounted packages with no special heatsinking (i.e., dual-in-line package mounted on lead seating plane with no contact between bottom of package and socket or P/C board and flat package mounted with bottom in direct contact with non-metallized area of P/C board).

The designer may want to use MECL devices under conditions other than those given above. The majority of the low-power device types may be used without air and with higher θ_{JA} . However, the designer must bear in mind that junction temperatures will be higher for higher θ_{JA} , even though the ambient temperature is the same. Higher junction temperatures will cause logic levels to shift.

As an example, a 300 mW 16 lead dual-in-line ceramic device operated at $\theta_{JA} = 100^\circ\text{C/W}$ (in still air) shows a HIGH logic level shift of about 21 mV above the HIGH logic level when operated with 500 lfpm air flow and a $\theta_{JA} = 50^\circ\text{C/W}$. (Level shift = $\Delta T_J \times 1.4 \text{ mV}/^\circ\text{C}$).

If logic levels of individual devices shift by different amounts (depending on P_D and θ_{JA}), noise margins are

somewhat reduced. Therefore, the system designer must lay out his system bearing in mind that the mounting procedures to be used should minimize thermal effects on noise margin.

The following sections on package mounting and heat-sinking are intended to provide the designer with sufficient information to insure good noise margins and high reliability in MECL system use.

MOUNTING AND HEATSINK SUGGESTIONS

With large high-speed logic systems, the use of multilayer printed circuit boards is recommended to provide both a better ground plane and a good thermal path for heat dissipation. Also, a multilayer board allows the use of microstrip line techniques to provide transmission line interconnections.

Two-sided printed circuit boards may be used where board dimensions and package count are small. If possible, the V_{CC} ground plane should face the bottom of the package to form the thermal conduction plane. If signal lines must be placed on both sides of the board, the V_{EE} plane may be used as the thermal plane, and at the same time may be used as a pseudo ground plane. The pseudo ground plane becomes the ac ground reference under the signal lines placed on the same side as the V_{CC} ground plane (now on the opposite side of the board from the packages), thus maintaining a microstrip signal line environment.

Two-ounce copper P/C board is recommended for thermal conduction and mechanical strength. Also, mounting holes for low power devices may be countersunk to allow the package bottom to contact the heat plane. This technique used along with thermal paste will provide good thermal conduction.

Printed channeling is a useful technique for conduction of heat away from the packages when the devices are soldered into a printed circuit board. As illustrated in Figure 20, this heat dissipation method could also serve as V_{EE} voltage distribution or as a ground bus. The channels should terminate into channel strips at each side or the rear of a plug-in type printed circuit board. The heat can then be removed from the circuit board, or board slide rack, by means of wipers that come into thermal contact with the edge channels.

FIGURE 20 — CHANNEL/WIPER HEATSINKING ON DOUBLE LAYER BOARD

For operating some of the higher power device types* in 16 lead dual-in-line packages in still air, requiring $\theta_{JA} < 100^\circ\text{C/W}$, a suitable heatsink is the IERC LIC-214A2WCB shown in Figure 21. This sink reduces the still air θ_{JA} to around 55°C/W . By mounting this heatsink directly on a copper ground plane (using silicone paste) and passing 500 lfm air over the packages, θ_{JA} is reduced to approximately 35°C/W , permitting use at higher ambient temperatures than $+85^\circ\text{C}$ ($+75^\circ\text{C}$ for MECL 10KH memories) or in lowering T_J for improved reliability.

FIGURE 21 — MECL HIGH-POWER DUAL-IN-LINE PACKAGE MOUNTING METHOD

It should be noted that the use of a heatsink on the top surface of the dual-in-line package is not very effective in lowering the θ_{JA} . This is due to the location of the die near the bottom surface of the package. Also, very little ($< 10\%$) of the internal heat is withdrawn through the package leads due to the isolation from the ceramic by the solder glass seals and the limited heat conduction from the die through 1.0 to 1.5 mil aluminum bonding wires.

INTERFACING MECL TO SLOWER LOGIC TYPES

MECL circuits are interfaceable with most other logic forms. For MECL/TTL/DTL interfaces, when MECL is operated at the recommended -5.2 volts and TTL/DTL at $+5.0$ V supply, currently available translator circuits, such as the MC10124 and MC10125, may be used.

For systems where a dual supply (-5.2 V and $+5$ V) is not practical, the MC10H350 includes four single supply MECL to TTL translators, or a discrete component translator can be designed. For details, see MECL System Design Handbook (HB205). Such circuits can easily be made fast enough for any available TTL.

* 10128, 10129, 10136, 10H136, 10137, 10177, 10182, and 10804, Max $P_D > 800$ mW.

MECL also interfaces readily with MOS. With CMOS operating at $+5$ V, any of the MECL to TTL translators works very well.

Specific circuitry for use in interfacing MECL families to other logic types is given in detail in the MECL System Design Handbook.

Complex MECL 10K devices are presently available for interfacing MECL with MOS logic, MOS memories, TTL three-state circuits, and IBM bus logic levels. See Application Note AN-720 for additional interfacing information.

CIRCUIT INTERCONNECTIONS

Though not necessarily essential, the use of multilayer printed circuit boards offers a number of advantages in the development of high-speed logic cards. Not only do multilayer boards achieve a much higher package density, interconnecting leads are kept shorter, thus minimizing propagation delay between packages. This is particularly beneficial with MECL III which has relatively fast (1 ns) rise and fall times. Moreover, the unbroken ground planes made possible with multilayer boards permit much more precise control of transmission line impedances when these are used for interconnecting purposes. Thus multilayer boards are recommended for MECL III layouts and are justified when operating MECL 10KH and MECL 10K at top circuit speed, when high-density packaging is a requirement, or when transmission line interconnects are used.

Point-to-point back-plane wiring without matched line terminations may be employed for MECL interconnections if line runs are kept short. At MECL 10K speeds, this applies to line runs up to 6 inches, for MECL 10KH and MECL III up to 1 inch (Maximum open wire lengths for less than 100 mV undershoot). But, because of the open-emitter outputs of MECL 10KH, MECL 10K and MECL III circuits, pull-down resistors are always required. Several ways of connecting such pull-down resistors are shown in Figure 22.

Resistor values for the connection in Figure 22a may range from 270 ohms to $k\Omega$ depending on power and load requirements. (See MECL System Design Handbook.) Power may be saved by connecting pull-down resistors in the range of 50 ohms to 150 ohms, to -2.0 Vdc, as shown in Figure 22b. Use of a series damping resistor, Figure 22c, will extend permissible lengths of unmatched-impedance interconnections, with some loss of edge speed.

With proper choice of the series damping resistor, line lengths can be extended to any length,** while limiting overshoot and undershoot to a predetermined amount. Damping resistors usually range in value from 10 ohms to 100 ohms, depending on the line length, fanout, and line impedance, the open emitter-follower outputs of MECL 10KH, MECL III and MECL 10K give the system designer all possible line driving options.

One major advantage of MECL over saturated logic is its capability for driving matched-impedance transmission lines. Use of transmission lines retains signal integrity over long distances. The MECL 10KH and MECL 10K emitter-follower output transistors will drive a 50-ohm transmission line terminated to -2.0 Vdc. This is the equivalent current load of 22 mA in the HIGH logic state and 6 mA in the LOW state.

** Limited only by line attenuation and band-width characteristics.

Parallel termination of transmission lines can be done in two ways. One, as shown in Figure 23a, uses a single resistor whose value is equal to the impedance (Z_0) of the line. A terminating voltage (V_{TT}) of -2.0 Vdc must be supplied to the terminating resistor.

Another method of parallel termination uses a pair of resistors, R1 and R2. Figure 23b illustrates this method. The following two equations are used to calculate the values of R1 and R2:

$$R1 = 1.6 Z_0$$

$$R2 = 2.6 Z_0$$

Another popular approach is the series-terminated transmission line (see Figure 23). This differs from parallel termination in that only one-half the logic swing is propagated through the lines. The logic swing doubles at the end of the transmission line due to reflection on an open line, again establishing a full logic swing.

FIGURE 22 — PULL-DOWN RESISTOR TECHNIQUES

To maintain clean wave fronts, the input impedance of the driven gate must be much greater than the characteristic impedance of the transmission line. This condition is satisfied by MECL circuits which have high impedance inputs. Using the appropriate terminating resistor (R_S) at point A (Figure 24), the reflections in the transmission line will be terminated.

FIGURE 23a — PARALLEL TERMINATED LINE

FIGURE 23b — PARALLEL TERMINATION — THEVENIN EQUIVALENT

FIGURE 24 — SERIES TERMINATED LINE

The advantages of series termination include ease of driving multiple series-terminated lines, low power consumption, and low cross talk between adjacent lines. The disadvantage of this system is that loads may not be distributed along the transmission line due to the one-half logic swing present at intermediate points.

For board-to-board interconnections, coaxial cable may be used for signal conductors. The termination techniques just discussed also apply when using coax. Coaxial cable has the advantages of good noise immunity and low attenuation at high frequencies.

Twisted pair lines are one of the most popular methods of interconnecting cards or panels. The complementary outputs of any MECL function may be connected to one end of the twisted pair line, and any MECL differential line receiver to the other as shown in the example, Figure 25. R_T is used to terminate the twisted pair line. The 1 to 1.5 V common-mode noise rejection of the line receiver ignores common-mode cross talk, permitting multiple twisted pair lines to be tied into cables. MECL signals may be sent very long distances (> 1000 feet) on twisted pair, although line attenuation will limit bandwidth, degrading edge speeds when long line runs are made.

If timing is critical, parallel signals paths (shown in Figure 26) should be used when fanout to several cards is required. This will eliminate distortion caused by long stub lengths off a signal path.

Wire-wrapped connections can be used with MECL 10K. For MECL III and MECL 10KH, the fast edge speeds (1 ns) create a mismatch at the wire-wrap connections which can cause reflections, thus reducing noise immunity. The mismatch occurs also with MECL 10K, but the distance between the wire-wrap connections and the end of the line is generally short enough so the reflections cause no problem.

Series damping resistors may be used with wire-wrapped lines to extend permissible backplane wiring lengths. Twisted pair lines may be used for even longer distances across large wire-wrapped cards. The twisted pair gives a more defined characteristic impedance (than a single wire), and can be connected either single-ended, or differentially using a line receiver.

The recommended wire-wrapped circuit cards have a ground plane on one side and a voltage plane on the other side to insure a good ground and a stable voltage source for the circuits. In addition, the ground plane near the wire-wrapped lines lowers the impedance of those lines and facilitates terminating the line. Finally, the ground plane serves to minimize cross talk between parallel paths in the signal lines. Point-to-point wire routing is recommended because cross talk will be minimized and line lengths will be shortest. Commercial wire-wrap boards designed for MECL 10K are available from several vendors.

FIGURE 25 — TWISTED PAIR LINE DRIVER/RECEIVER

FIGURE 26 — PARALLEL FANOUT TECHNIQUES

Microstrip and Stripline

Microstrip and stripline techniques are used with printed circuit boards to form transmission lines. Microstrip consists of a constant-width conductor on one side of a circuit board, with a ground plane on the other side (shown in Figure 27). The characteristic impedance is determined by the width and thickness of the conductor, the thickness of the circuit board, and the dielectric constant of the circuit board material.

FIGURE 27 — PC INTERCONNECTION LINES FOR USE WITH MECL

Stripline is used with multilayer circuit boards as shown in Figure 27. Stripline consists of a constant-width conductor between two ground planes.

Refer to MECL System Design Handbook for a full discussion of the properties and use of these.

CLOCK DISTRIBUTION

Clock distribution can be a system problem. At MECL 10K speeds, either coaxial cable or twisted pair line (using the MC10101 and MC10115) can be used to distribute clock signals throughout a system. Clock line lengths should be controlled and matched when timing could be critical. Once the clocking signals arrive on card, a tree distribution should be used for large-fanouts at high frequency. An example of the application of the technique is shown in Figure 28.

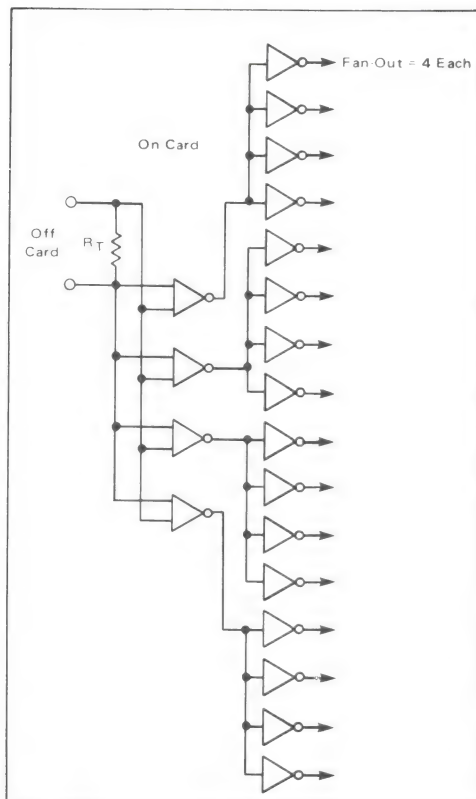

Because of the very high clock rates encountered in MECL III systems, rules for clocking are more rigorous than in slower systems.

The following guidelines should be followed for best results:

A. On-card Synchronous Clock Distribution via Transmission Line

1. Use the NOR output in developing clock chains or trees. Do not mix OR and NOR outputs in the chain.
2. Use balanced fanouts on the clock drivers.
3. Overshoot can be reduced by using two parallel drive lines in place of one drive line with twice the lumped load.

FIGURE 28 — 64 FANOUT CLOCK DISTRIBUTION
(PROPER TERMINATION REQUIRED)

4. To minimize clock skewing problems on synchronous sections of the system, line delays should be matched to within 1 ns.

5. Parallel drive gates should be used when clocking repetition rates are high, or when high capacitance loads occur. The bandwidth of a MECL III gate may be extended by paralleling both halves of a dual gate. Approximately 40 or 50 MHz bandwidth can be gained by paralleling two or three clock driver gates.

6. Fanout limits should be applied to clock distribution drivers. Four to six loads should be the maximum load per driver for best high speed performance. Avoid large lumped loads at the end of lines greater than 3 inches. A lumped load, if used, should be four or fewer loads.

7. For wire-OR (emitter dotting), two-way lines (busses) are recommended. To produce such lines, both ends of a transmission line are terminated with 100-ohms impedance. This method should be used when wire-OR connections exceed 1 inch apart on a drive line.

B. Off-Card Clock Distribution

1. The OR/NOR outputs of an MC1660 may be used to drive into twisted pair lines or into flat, fixed-impedance ribbon cable. At the far end of the twisted pair on MC1692 differential line receiver is used. The line should be terminated as shown in Figure 25. This method not only provides high speed, board-to-board clock distribution, but also provides system noise margin advantages. Since the line receiver operates independently of the V_{BB} reference voltage (differential inputs) the noise margin from board to board is also independent of temperature differentials.

LOGIC SHORTCUTS

MECL circuitry offers several logic design conveniences. Among these are:

1. **Wire-OR** (can be produced by wiring MECL output emitters together outside packages).

2. **Complementary Logic Outputs** (both OR and NOR are brought out to package pins in most cases).

An example of the use of these two features to reduce gate and package count is shown in Figure 29.

The connection shown saves several gate circuits over performing the same functions with non-ECL type logic. Also, the logic functions in Figure 29 are all accomplished with one gate propagation delay time for best system speed. Wire-ORing permits direct connections of MECL circuits to busses. (MECL System Design Handbook and Application Note AN-726).

Propagation delay is increased approximately 50 ps per wire-OR connection. In general, wire-OR should be limited to 6 MECL outputs to maintain a proper LOW logic level. The MC10123 is an exception to this rule because it has a special V_{OL} level that allows very high fanout on a bus or wire-OR line. The use of a single output pull-down resistor is recommended per wire-OR, to economize on power dissipation. However, two pull-down resistors per wired-OR can improve fall times and be used for double termination of busses.

Wire-OR should be done between gates in a package or nearby packages to avoid spikes due to line propagation delay. This does not apply to bus lines which activate only one driver at a time.

FIGURE 29 — USE OF WIRE-OR AND
COMPLEMENTARY OUTPUTS

SYSTEM CONSIDERATIONS — A SUMMARY OF RECOMMENDATIONS

	MECL 10KH	MECL 10K	MECL III
Power Supply Regulation	$\pm 5\%$ (1)	10% (2)	10% (2)
On-Card Temperature Gradient	20 C	Less Than 25°C	Less Than 25°C
Maximum Non-Transmission Line Length (No Damping Resistor)	1"	8"	1"
Unused Inputs	Leave Open (3)	Leave Open (3)	Leave Open (3)
PC Board	Multilayer	Standard 2-Sided or Multilayer	Multilayer
Cooling Requirements	500 lfpm Air	500 lfpm Air	500 lfpm Air
Bus Connection Capability	Yes (Wire-OR)	Yes (Wire-OR)	Yes (Wire-OR)
Maximum Twisted Pair Length (Differential Drive)	Limited By Cable Response Only, Usually $>1000'$	Limited by Cable Response Only, Usually $>1000'$	Limited by Cable Response Only, Usually $>1000'$
The Ground Plane to Occupy Percent Area of Card	$>75\%$	$>50\%$	$>75\%$
Wire Wrap may be used	Not Recommended	Yes	Not Recommended
Compatible with MECL 10,000	Yes	—	Yes

(1) All dc and ac parameters guaranteed for $V_{EE} = -5.2 \text{ V} \pm 5\%$.

(2) At the devices (functional only).

(3) Except special functions without input pull-down resistors.

PACKAGE OUTLINE DIMENSIONS

A letter suffix to the MECL logic function part number is used to specify the package style (see drawings below). See appropriate selector guide for specific packaging available for a given device type.

MECL Logic Surface Mount

WHY SURFACE MOUNT?

Surface Mount Technology is now being utilized to offer answers to many problems that have been created in the use of insertion technology.

Limitations have been reached with insertion packages and PC board technology. Surface Mount Technology offers the opportunity to continue to advance the State-of-the-Art designs that cannot be accomplished with Insertion Technology.

Surface Mount Packages allow more optimum device performance with the smaller Surface Mount configuration. Internal lead lengths, parasitic capacitance and inductance that placed limitations on chip performance have been reduced.

The lower profile of Surface Mount Packages allows more boards to be utilized in a given amount of space. They are stacked closer together and utilize less total volume than insertion populated PC boards.

Printed circuit costs are lowered with the reduction of the number of board layers required. The elimination or reduction of the number of plated through holes in the board, contribute significantly to lower PC board prices.

Surface Mount assembly does not require the preparation of components that are common on insertion technology lines. Surface Mount components are sent directly to the assembly line, eliminating an intermediate step.

Automatic placement equipment is available that can place Surface Mount components at the rate of a few thousand per hour to hundreds of thousands of components per hour.

Surface Mount Technology is cost effective, allowing the manufacturer the opportunity to produce smaller units and offer increased functions with the same size product.

MECL AVAILABILITY IN SURFACE MOUNT

Motorola is now offering MECL 10K and MECL 10KH in the PLCC (Plastic Leaded Chip Carrier) packages.

MECL in PLCC may be ordered in conventional plastic rails or on Tape and Reel. Refer to the Tape and Reel section for ordering details.

TAPE AND REEL

Motorola has now added the convenience of Tape and Reel packaging for our growing family of standard Integrated Circuit products. The packaging fully conforms to

the latest EIA RS-481A specification. The antistatic embossed tape provides a secure cavity sealed with a peel-back cover tape.

GENERAL INFORMATION

- Reel Size 13 inch (330 mm) Suffix: R2
- Tape Width 16 mm
- Units/Reel 1000

MECHANICAL POLARIZATION

ORDERING INFORMATION

- Minimum Lot Size/Device Type = 3000 Pieces.
- No Partial Reel Counts Available.
- To order devices which are to be delivered in Tape and Reel, add the appropriate suffix to the device number being ordered.

EXAMPLE:

ORDERING CODE

MC10100FN
MC10100FNR2
MC10H100FN

MECL 10KH INTRODUCTION

Motorola's new MECL 10KH family features 100% improvement in propagation delay and clock speeds while maintaining power supply current equal to MECL 10K. This new MECL family is voltage compensated which allows guaranteed dc and switching parameters over a $\pm 5\%$ power supply range. Noise margins of MECL 10KH are 75% better than the MECL 10K series over the $\pm 5\%$ power supply range. MECL 10KH is compatible with MECL 10K and MECL III, a key element in allowing users to enhance existing systems by increasing the speed in critical timing areas. Also, many MECL 10KH devices are pinout/functional duplications of the MECL 10K series devices.

FIGURE 1 — MECL 10K versus MECL 10KH GATE DESIGN

The schematics in Figure 1 compare the basic gate structure of the MECL 10KH to that of MECL 10K devices. The gate switch current is established with a current source in the MECL 10KH family as compared to a resistor source in MECL 10K. The bias generator in the MECL 10K device has been replaced with a voltage regulator in the MECL 10KH series. The advantages of these design changes are: current-sources permit-matched collector resistors that yield correspondingly better matched delays, less variation in the output-voltage level with power supply changes, and matched output-tracking rates with temperature. These circuit changes increase complexity at the gate level; however, the added performance more than compensates.

The MECL 10KH family is being fabricated using Motorola's MOSAIC I (Motorola Oxide Self Aligned Implanted Circuits). The switching transistor's geometries obtained in the MOSAIC I process show a two-fold improvement in τ_T , a reduction of more than 50% in parasitic capacitance and a decrease in device area of almost 76%.

FIGURE 2 — MOSAIC versus MECL 10K SWITCHING TRANSISTOR GEOMETRY

With improved geometry, the MECL 10KH switching transistors (left) are one-seventh the size of the older MECL 10K transistors (right). Along with the smaller area comes an improved f_T and reduced parasitic capacitances.

Figure 2 illustrates the relative size difference between the junction isolated transistor of MECL 10K and the MOSAIC I transistor of MECL 10KH. This suggests that performance could be improved twofold at lower power levels. However, at the gate level, the power of the output transistor cannot be reduced without sacrificing output characteristics because of the 50 ohm drive requirements of MECL. In more complex functions, where part of the delay is associated with internal gates, MECL 10KH devices use less power than the equivalent MECL 10K devices and provide an even more significant improvement in ac performance.

Table 1. — TYPICAL FAMILY CHARACTERISTICS FOR 10K AND 10KH CIRCUITS

	10K	10KH
Propagation delay (ns)	2.0	1.0
Power (mW)	25	25
Power-speed product (pJ)	50	25
Rise/fall times (ns)	2.0	1.0
(20–80%)		
Temperature range (°C)	–30 to +85	0 to +75
Voltage regulated	No	Yes
Technology	Junction isolated	Oxide isolated
$V_{EE} = -5.2 \text{ V}$		

Supply & Temperature Variation

MECL 10KH temperature and voltage compensation is designed to guarantee compatibility with MECL 10K, MECL III, MECL Memories and the MC10900 and Macrocell Array products. Table 1 summarizes some performance characteristics of the MECL 10K and 10KH logic families in a 16-pin DIP. The MECL 10KH devices offer typical propagation delays of 1.0 ns at 25 mW per gate when operated from a V_{EE} of -5.2 V. The resulting speed-power product of 25 picojoules is the best of any ECL logic family available today.

The operating temperature range is changed from -30°C to $+85^{\circ}\text{C}$ of the MECL 10K family to the narrower range of 0°C to 75°C for MECL 10KH. This change matches the constraints established by the memory and array products. Operation at -30°C would require compromises in performance and power. With few exceptions, commercial applications are satisfied by 0°C min.

Table 2. — MECL 10KH AC SPECIFICATIONS AND TRACKING

Parameter	0°C			25°C			75°C			Units
	Min	Typ	Max	Min	Typ	Max	Min	Typ	Max	
t_{PD}	0.4	1.0	1.5	0.4	1.0	1.6	0.4	1.0	1.7	ns
t_R (20–80%)	Min	Max		Min	Max		Min	Max		ns
	0.5	1.5		0.5	1.6		0.5	1.7		
t_F (20–80%)	0.5	1.5		0.5	1.6		0.5	1.7		ns
$V_{EE} = -5.2 \text{ V} \pm 5\%$										
Parameter	Propagation delay (ns)*		Delay variation vs temp (ps/°C)		Delay variation vs supply (ps/V)					
	Typ	Max	Typ	Max	Typ	Max				
t_{PD}	10K		2.0	2.9	2.0	7.0	80			
	10KH		1.0	1.5	0.5	4.0	0			

* $V_{EE} = -5.2 \text{ V}$, Temp = 25°C

AC specifications of MECL 10KH products appear in Table 2. In the MECL 10KH family, all ac specifications have guaranteed minimums and maximums for extremes of both temperature and supply — a first in ECL logic. In addition, flip flops, latches and counters will have guaranteed limits for setup time, hold time, and clock pulse width. The limits in Table 2 are guaranteed for a power supply variation of $\pm 5\%$. MECL 10K typically has a propagation delay (t_{PD}) variation of 80 ps/V with no guaranteed maximum. The typical variation in t_{PD} for MECL 10KH circuits is only 38 ps typically over the entire specified temperature range and power-supply tolerance, and is guaranteed not to exceed 300 ps.

The improved performance in temperature over MECL 10K are a result of the internal voltage regulator. The primary difference being the flatter tracking rate of the output "0" level voltage (V_{OL}). This difference does not affect the compatibility with existing MECL families.

Changes in output "1" level voltages (V_{OH}) with supply variations are 10 mV/V less for the MECL 10KH family. V_{OH} varies with the supply, primarily because of changes in chip temperature caused by the changes in power dissipation. However, the current in the MECL 10KH circuits remains almost constant with supply changes, since the circuits are voltage compensated and use current sources for all internal emitter followers. Threshold voltage (V_{BB})

Table 3. — LOGIC LEVEL DC TRACKING RATE FOR 10K AND 10KH CIRCUITS

		Min	Typ	Max
$\Delta V_{OH}/\Delta T$ (mV/°C)	10KH	1.2	1.3	1.5
	10K	1.2	1.3	1.5
$\Delta V_{BB}/\Delta T$ (mV/°C)	10KH	0.8	1.0	1.2
	10K	0.8	1.0	1.2
$\Delta V_{OL}/\Delta T$ (mV/°C)	10KH	0	0.4	0.6
	10K	0.35	0.5	0.75
		0.75	1.0	1.55
$\Delta V_{OH}/\Delta V_{EE}$ (mV/V)	10KH	-20		0
	10K	-30		0
$\Delta V_{BB}/\Delta V_{EE}$ (mV/V)	10KH	0	10	25
	10K	110	150	190
$\Delta V_{OL}/\Delta V_{EE}$ (mV/V)	10KH	0	20	50
	10K	200	250	320

and output "0" level voltage (V_{OL}) variations are shown with respect to MECL 10K in Table 3. In both cases voltage compensation has reduced the variations significantly.

Noise Margin Considerations

Specification of input voltage levels (V_{IH} , V_{IL}) are changed from those of MECL 10K resulting in improved noise margins for MECL 10KH.

The MECL 10K circuits have two sets of output voltage specifications (V_{OH} , V_{OHA} and V_{OL} , V_{OLA}). The first output voltage specification in each set (V_{OH} and V_{OL}) are guaranteed maximum and minimum output levels for typical input levels. The second specification in each set (V_{OHA} and V_{OLA}) is the guaranteed worst-case output level for input threshold voltages. System analysis for worst-case noise margin considers V_{OHA} and V_{OLA} only. The MECL 10KH family has only one set of output voltages (V_{OH} and V_{OL}) with minimum and maximum values specified. The minimum value of V_{OH} and the maximum value for V_{OL} of the MECL 10KH family is synonymous with the V_{OHA} and V_{OLA} specifications of MECL 10K family.

The V_{OH} values for the MECL 10KH circuits are equal to or better than the MECL 10K levels at all temperatures. Input threshold voltages (V_{IH} and V_{IL}), which are synonymous with V_{IH} min and V_{IL} max for 10KH) are also improved and guaranteed V_{IH} has been decreased by 25 mV over the entire operating temperature range, resulting in a "1" level noise margin of 150 mV (compared to

Table 4. — NOISE MARGIN versus POWER-SUPPLY CONDITIONS

Parameter		$V_{EE} - 10\%$		$V_{EE} - 5\%$		V_{EE}		$V_{EE} + 5\%$	
		Typ	Min	Typ	Min	Typ	Min	Typ	Min
Noise Margin High	10KH	224	150	227	150	230	150	233	150
V_{NH} (mV)	10K	127	47	166	86	205	125	241	164
Noise Margin Low	10KH	264	150	267	150	270	150	273	150
V_{NL} (mV)	10K	223	103	249	129	275	155	301	181

*Temp = 0 to 75°C

125 mV for the MECL 10K circuits). V_{ILA} has been decreased by 5.0 mV, providing a "0" level noise margin equal to the "1" level noise margin. The V_{OL} minimum of the MECL 10KH is more negative than for MECL 10K (-1950 mV instead of -1850 mV). The V_{OL} level for the MECL 10K family was selected to ensure that the gate would not saturate at high temperatures and high supply voltages. The reduction in operating temperature range for the MECL 10KH family and the improvement in tracking rate allow the lower V_{OL} level. The change in this level does not affect system noise margins. Although some of the interface levels change with temperature, the changes in voltage levels are well within the tolerance ranges that would keep the families compatible. Table 4 lists some noise margins for V_{EE} supply variations.

The compatibility of MECL 10KH with MECL 10K may be demonstrated by applying the tracking rates in Table 3 to the dc specifications. The method for determining compatibility is to show acceptable noise margins for MECL 10KH, MECL 10K and mixed MECL 10K/MECL 10KH systems. The assumption is that the families are compatible if the noise margin for a mixed system is equal to or better than the same system using only the MECL 10K series.

Using an all MECL 10K system as a reference, three possible logic mixes must be considered: MECL 10K driving MECL 10KH; MECL 10KH driving MECL 10K; and MECL 10KH driving MECL 10KH. The system noise margin for the three configurations can now be calculated for the following cases (See Figure 3):

In Case 1, the system uses multiple power supplies, each independently voltage regulated to some percentage tolerance. Worst-case is where one device is at the plus extreme and the other device is at the minus extreme of the supply tolerance.

In Case 2, a system operates on a single supply or several supplies slaved to a master supply. The entire system can drift, but all devices are at the same supply voltage.

In Case 3, a system has excessive supply drops throughout. Supply gradients are due to resistive drops in V_{EE} bus.

The analysis indicates that the noise margins for a MECL 10K/10KH system equal or exceed the margins for an all 10K system for supply tolerance up to $\pm 5\%$. The results of the analysis are shown in Figure 3.

MOTOROLA

MC10H115

QUAD LINE RECEIVER

The MC10H115 is a quad differential amplifier designed for use in sensing differential signals over long lines. This 10KH part is a functional/pinout duplication of the standard MECL 10K family part, with 100% improvement in counting frequency and no increase in power-supply current.

The base bias supply (V_{BB}) is made available at Pin 9 to make the device useful as a Schmitt trigger, or in other applications where a stable reference voltage is necessary. Active current sources provide the MC10H115 with excellent common mode rejection. If any amplifier in a package is not used, one input of that amplifier must be connected to V_{BB} (Pin 9) to prevent upsetting the current source bias network.

- Propagation Delay, 1.0 ns Typical
- Power Dissipation 110 mW Typ/Pkg (No Load)
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

PLASTIC PACKAGE
CASE 648

FN SUFFIX
PLCC
CASE 775

LOGIC DIAGRAM

V_{CC1} = Pin 1
 V_{CC2} = Pin 16
 V_{EE} = Pin 8

When input pin with bubble goes positive it's respective output pin with bubble goes positive.

* V_{BB} to be used to supply bias to the MC10H116 only and bypassed (when used) with 0.01 μF to 0.1 μF capacitor.

The MC10H116 is designed to be used in sensing differential signals over long lines. The bias supply (V_{BB}) is made available to make the device useful as a Schmitt trigger, or in other applications where a stable reference voltage is necessary.

Active current sources provide these receivers with excellent common-mode noise rejection. If any amplifier in a package is not used, one input of that amplifier must be connected to V_{BB} to prevent unbalancing the current-source bias network.

The MC10H116 does not have internal input pull-down resistors. This provides high impedance to the amplifier input and facilitates differential connections.

Applications:

- Low Level Receiver
- Voltage Level Interface
- Schmitt Trigger

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

MOTOROLA

MC10H117

DUAL 2-WIDE 2-3-INPUT "OR-AND/OR-AND-INVERT" GATE

The MC10H117 is a general purpose logic element designed for use in data control, such as digital multiplexing or data distribution. Pin 9 is common to both gates. This MECL 10KH part is a functional/pinout duplication of the standard MECL 10K family part, with 100% improvement in propagation delay, and no increase in power-supply current.

- Propagation Delay, 1.0 ns Typical
- Power Dissipation 100 mW/Gate Typical (same as MECL 10K)
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

Each MECL 10KH series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts.

MOTOROLA

MC10H118

DUAL 2-WIDE 3-INPUT "OR-AND" GATE

The MC10H118 is a basic logic building block providing the OR/AND function, useful in data control and digital multiplexing applications. This MECL 10KH part is a functional/pinout duplication of the standard MECL 10K family part, with 100% improvement in propagation delay, and no increase in power-supply current.

- Propagation Delay, 1.0 ns Typical
- Power Dissipation 100 mW/Gate Typical (same as MECL 10K)
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

MOTOROLA

MC10H123

TRIPLE 4-3-3 INPUT BUS DRIVER

The MC10H123 is a triple 4-3-3 Input Bus Driver.

The MC10H123 consists of three NOR gates designed for bus driving applications on card or between cards. Output low logic levels are specified with $V_{OL} = -2.1$ Vdc so that the bus may be terminated to -2.0 Vdc. The gate output, when low, appears as a high impedance to the bus, because the output emitter-followers of the MC10H123 are "turned-off." This eliminates discontinuities in the characteristic impedance of the bus.

The V_{OH} level is specified when driving a 25-ohm load terminated to -2.0 Vdc, the equivalent of a 50-ohm bus terminated at both ends. Although 25 ohms is the lowest characteristic impedance that can be driven by the MC10H123, higher impedance values may be used with this part. A typical 50-ohm bus is shown in Figure 1.

- Propagation Delay, 1.5 ns Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

 For PLCC pin assignment, see tables on page 1-31.

APPLICATIONS INFORMATION

The MC10H124 has TTL-compatible inputs and MECL complementary open-emitter outputs that allow use as an inverting/non-inverting translator or as a differential line driver. When the common strobe input is at the low-logic level, it forces all true outputs to a MECL low-logic state and all inverting outputs to a MECL high-logic state.

An advantage of this device is that TTL-level information can be transmitted differentially, via balanced twisted pair lines, to MECL equipment, where the signal can be received by the MC10H115 or MC10H116 differential line receivers. The power supply requirements are ground, +5.0 volts, and -5.2 volts.

MOTOROLA

MC10H125

QUAD MECL-TO-TTL TRANSLATOR

The MC10H125 is a quad translator for interfacing data and control signals between the MECL section and saturated logic section of digital systems. The 10KH part is a functional/pinout duplication of the standard MECL 10K family part, with 100% improvement in propagation delay, and no increase in power-supply current.

- Propagation Delay, 2.5 ns Typical
- Voltage Compensated
- Improved Noise Margin 150 mV
- MECL 10K-Compatible (Over Operating Voltage and Temperature Range)

 V_{EE} (-5.2 Vdc) = Pin 8

* V_{BB} to be used to supply bias to the MC10H125 only and bypassed (when used) with 0.01 μ F to 0.1 μ F capacitor.

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

APPLICATION INFORMATION

The MC10H125 incorporates differential inputs and Schottky TTL "totem pole" outputs. Differential inputs allow for use as an inverting/non-inverting translator or as a differential line receiver. The V_{BB} reference voltage is available on Pin 1 for use in single-ended input biasing. The outputs of the MC10H125 go to a low-logic

level whenever the inputs are left floating.

An advantage of this device is that MECL-level information can be received, via balanced twisted pair lines, in the TTL equipment. This isolates the MECL-logic from the noisy TTL environment. Power supply requirements are ground, +5.0 volts and -5.2 volts.

MOTOROLA

DUAL LATCH

The MC10H130 is a MECL 10KH part which is a functional/pinout duplication of the standard MECL 10K family part, with 100% improvement in clock speed and propagation delay and no increase in power-supply current.

- Propagation Delay, 1.0 ns Typical
- Power Dissipation, 155 mW Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

APPLICATION INFORMATION

The MC10H130 is a clocked dual D type latch. Each latch may be clocked separately by holding the common clock in the low state, and using the clock enable inputs for the clocking function. If the common clock is to be used to clock the latch, the clock enable (\overline{CE}) inputs must be in the low state. In this mode, the enable inputs perform the function of controlling the common clock (\overline{C}).

Any change at the D input will be reflected at the output

while the clock is low. The outputs are latched on the positive transition of the clock. While the clock is in the high state, a change in the information present at the data inputs will not affect the output information.

The set and reset inputs do not override the clock and D inputs. They are effective only when either \overline{C} or \overline{CE} or both are high.

MOTOROLA

DUAL TYPE D MASTER-SLAVE FLIP-FLOP

The MC10H131 is a MECL 10KH part which is a functional/pinout duplication of the standard MECL 10K family part, with 100% improvement in clock speed and propagation delay and no increase in power-supply current.

- Propagation Delay, 1.0 ns Typical
- Power Dissipation, 235 mW Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

A clock H is a clock transition from a low to a high state.

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

APPLICATION INFORMATION

The MC10H131 is a dual master-slave type D flip-flop. Asynchronous Set (S) and Reset (R) override Clock (C_C) and Clock Enable (\overline{CE}) inputs. Each flip-flop may be clocked separately by holding the common clock in the new low state and using the enable inputs for the clocking function. If the common clock is to be used to clock the flip-flop, the Clock Enable inputs must be in the low state.

In this case, the enable inputs perform the function of controlling the common clock.

The output states of the flip-flop change on the positive transition of the clock. A change in the information present at the data (D) input will not affect the output information at any other time due to master slave construction.

MOTOROLA

DUAL J-K MASTER SLAVE FLIP-FLOP

The MC10H135 is a dual J-K master slave flip-flop. The device is provided with an asynchronous set(s) and reset(R). These set and reset inputs override the clock.

A common clock is provided with separate \bar{J} - \bar{K} inputs. When the clock is static, the JK inputs do not effect the output. The output states of the flip flop change on the positive transition of the clock.

- Propagation Delay, 1.5 ns Typical
- Power Dissipation, 280 mW Typical/Pkg. (No Load)
- f_{tog} 250 MHz Max
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated

MC10H136

LOGIC DIAGRAM

NOTE: FLIP FLOPS WILL TOGGLE WHEN ALL \bar{T} INPUTS ARE LOW

APPLICATION INFORMATION

The MC10H136 is a high speed synchronous counter that operates at 250 MHz. Counter operating modes include count up, count down, pre-set and hold count. This device allows the designer to use one basic counter for many applications.

The S1, S2, control lines determine the operating modes of the counter. In the pre-set mode, a clock pulse is necessary to load the counter with the information present on the data inputs (D0, D1, D2, and D3). Carry out goes low on the terminal count or when the counter is being pre-set.

MOTOROLA

FOUR-BIT UNIVERSAL SHIFT REGISTER

The MC10H141 is a four-bit universal shift register. This device is a functional/pinout duplication of the standard MECL 10K part with 100% improvement in propagation delay and operation frequency and no increase in power supply current.

- Shift frequency, 250 MHz Min
- Power Dissipation, 425 mW Typical

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

LOGIC DIAGRAM

APPLICATION INFORMATION

The MC10H141 is a four-bit universal shift register which performs shift left, or shift right, serial/parallel in, and serial/parallel out operations with no external gating. Inputs S1 and S2 control the four possible operations of the register without external gating of the clock. The flip-flops shift information on the positive edge of

the clock. The four operations are stop shift, shift left, shift right, and parallel entry of data. The other six inputs are all data type inputs; four for parallel entry data, and one for shifting in from the left (DL) and one for shifting in from the right (DR).

MOTOROLA

MC10H145

Advance Information

16 x 4 BIT REGISTER FILE

The MC10H145 is a 16 x 4 bit register file. The active-low chip select allows easy expansion.

The operating mode of the register file is controlled by the \overline{WE} input. When \overline{WE} is "low" the device is in the write mode, the outputs are "low" and the data present at D_n input is stored at the selected address, when \overline{WE} is "high," the device is in the read mode — the data state at the selected location is present at the Q_n outputs.

- Address Access Time, 3.5 ns Typical
- Power Dissipation, 700 mW Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated

MOTOROLA

Advance Information

CONTENT ADDRESSABLE MEMORY

The MC10H155 is a 16-bit ECL Content Addressable Memory (CAM). The device is organized as an array of 8 words by 2 bits with each cell of the array containing an exclusive-OR comparator, a D-type latch as well as control logic. The modes of operation possible with the MC10H155 are reading, writing, associate, masked associate and the hybrid mode.

- Associate Time 7.0 ns Max
- Single Bit Masking
- Open Emitter Match Lines for Easy Bit Expansion
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

MAXIMUM RATINGS

Hybrid ⁵	1	0	1/0	1/0	0	0	I1	Qn0	$I1 \cdot \bar{Y}n$	$Qn0 \oplus I0$
Hybrid ⁵	0	1	1/0	1/0	0	I0	0	$I0 \cdot \bar{Y}n$	Qn1	$Qn1 \oplus I1$

X = Don't Care

Qn0 = Contents of Address n, Bit 0 (n = 0 to 7)

Qn1 = Contents of Address n, Bit 1

NOTES:

1. 1 (High) = Mismatch of $Qn \oplus I$, 0 (Low) = Match of $Qn \oplus I$
2. $D0 = Q00 \cdot \bar{Y}0 + Q10 \cdot \bar{Y}1 + \dots + Q70 \cdot \bar{Y}7$
 $D1 = Q01 \cdot \bar{Y}0 + Q11 \cdot \bar{Y}1 + \dots + Q71 \cdot \bar{Y}7$
3. Under normal operation, only one Y address is selected for read or write.
4. The write is transparent.
5. At all "matched" addresses there exists a simultaneous Associate and Write.

DESCRIPTION OF MODES OF OPERATION

The MC10H155 can be operated in any of the following modes: Read, Write, Associate, Masked Associate and Hybrid. Lines Y0–Y7 can be used as either inputs (a linear word select in the read/write mode) or as outputs (indicating match/mismatch in the associate mode).

Associate

Data present on the I0 and I1 inputs are compared with the latch outputs (Qn0, Qn1) of each cell. If the data input is at the same state as the latch output of a particular Y location, that Y-line goes low. Because these Y outputs are open emitters, expansion in multiples of 2 bits is obtained by tying additional MC10H155's to the Y-bus lines.

Masked Associate

This mode allows only the comparison of a single bit which is selected by bringing the corresponding A0- or A1-line high. The other bit is inhibited by holding the corresponding A0- or A1-line low.

Read

The particular cell output to be read is selected by bringing the associated Y-input low. Under normal op-

eration only one cell is selected to be read, all Y-inputs of deselected cells must be held high. The state of the selected cell appears on outputs D0 and D1. In the case where more than one cell is selected, the outputs of these cells are OR-ed together and appear on the D0-, D1-outputs.

Write

In this mode data present at the I0-, I1-inputs is transferred to the latch outputs. Since the D0-, D1-outputs are transparent, they follow the state of these I0-, I1-inputs. The particular cells to be written into are selected by taking their respective Y-inputs low. All deselected cells, Y-inputs must be held high.

Hybrid

In this mode, only one of the I0- or I1-data inputs are associated with their respective latch outputs, Qn0 or Qn1. If a match exists, the corresponding Yn-line(s) will go low. As the Y-line goes low, this will address the other half of the memory for writing new data. Thus, when I0 matches Qn0, it is possible to write I1 in Qn1 or vice versa.

MOTOROLA

MC10H158

QUAD 2-INPUT MULTIPLEXER (NON-INVERTING)

The MC10H158 is a quad two channel multiplexer with common input select. A "high" level select enables input D00, D10, D20 and D30 and a "low" level select enables input D01, D11, D21 and D31. This MECL 10KH part is a functional/pinout duplication of the standard MECL 10K family part, with 100% improvement in propagation delay and no increase in power-supply current.

- Propagation Delay, 1.5 ns Typical
- Power Dissipation, 197 mW Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

APPLICATION INFORMATION

The MC10H159 is a quad two channel multiplexer with enable. It incorporates common enable and common data select inputs. The select input determines which data inputs are enabled. A high (H) level enables data inputs

D0 0, D1 0, D2 0, and D3 0. A low (L) level enables data inputs D0 1, D1 1, D2 1, and D3 1. Any change on the data inputs will be reflected at the outputs while the enable is low. Input levels are inverted at the output.

LOGIC DIAGRAM

MC10H160

12-BIT PARITY GENERATOR-CHECKER

The MC10H160 is a 12-bit parity generator-checker. The output goes high when an odd number of inputs are high providing the odd parity function. Unconnected inputs are pulled to a logic low allowing parity detection and generation for less than 12 bits. The MC10H160 is a functional pin duplication of the standard 10K family part with 100% improvement in propagation delay and no increase in power-supply current.

- Propagation Delay, 2.5 ns Typical
- Power Dissipation, 320 mW Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

The MC10H161 provides parallel decoding of a three bit binary word to one of eight lines. The MC10H161 is useful in high-speed multiplexer/demultiplexer applications.

The MC10H161 is designed to decode a three bit input word to one of eight output lines. The MC10H161 output will be low when selected while all other output are high. The enable inputs, when either or both are high, force all outputs high.

The MC10H161 is a true parallel decoder. This eliminates unequal parallel path delay times found in other decoder designs. These devices are ideally suited for multiplexer/demultiplexer applications.

- Propagation Delay, 1.0 ns Typical
- Power Dissipation, 315 mW Typical (same as MECL 10K)
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

code present on inputs 7, 9, 14 of the MC10H161 and the A, B, C inputs of the MC10H164.

MOTOROLA

BINARY TO 1-8 DECODER (HIGH)

The MC10H162 provides parallel decoding of a three bit binary word to one of eight lines. The MC10H162 is useful in high-speed multiplexer/demultiplexer applications.

The MC10H162 is designed to decode a three bit input word to one of eight output lines. The MC10H162 output will be high when selected while all other output are low. The enable inputs, when either or both are high, force all outputs low.

The MC10H162 is a true parallel decoder. This eliminates unequal parallel path delay times found in other decoder designs. These devices are ideally suited for multiplexer/demultiplexer applications.

- Propagation Delay, 1.0 ns Typical
- Power Dissipation, 315 mW Typical (same as MECL 10K)
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

TYPICAL APPLICATIONS

FIGURE 1 – HIGH SPEED 16-BIT MULTIPLEXER/DEMULTIPLEXER

MOTOROLA

MC10H164

8-LINE MULTIPLEXER

The MC10H164 is a MECL 10KH part which is a functional pinout duplication of the standard MECL 10K family part, with 100% improvement in propagation delay, and no increase in power supply current.

The MC10H164 is designed to be used in data multiplexing and parallel to serial conversion applications. Full parallel gating provides equal delays through any data path. The MC10H164 incorporates an output buffer, eight inputs and an enable. A high on the enable forces the output low. The open emitter output allows the MC10H164 to be connected directly to a data bus. The enable line allows an easy means of expanding to more than 8 lines using additional MC10H164's.

- Propagation Delay, 1.0 ns Typical
- Power Dissipation, 310 mW Typical (same as MECL 10K)
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

8-INPUT PRIORITY ENCODER

The MC10H165 is a device designed to encode eight inputs to a binary coded output. The output code is that of the highest order input. Any input of lower priority is ignored. Each output incorporates a latch allowing synchronous operation. When the clock is low the outputs follow the inputs and latch when the clock goes high. This device is very useful for a variety of applications in checking system status in control processors, peripheral controllers, and testing systems.

The input is active when high, (e.g., the three binary outputs are low when input D0 is high). The Q3 output is high when any input is high. This allows direct extension into another priority encoder when more than eight inputs are necessary. The MC10H165 can also be used to develop binary codes from random logic inputs, for addressing ROMs, RAMs, or for multiplexing data.

LOGIC DIAGRAM

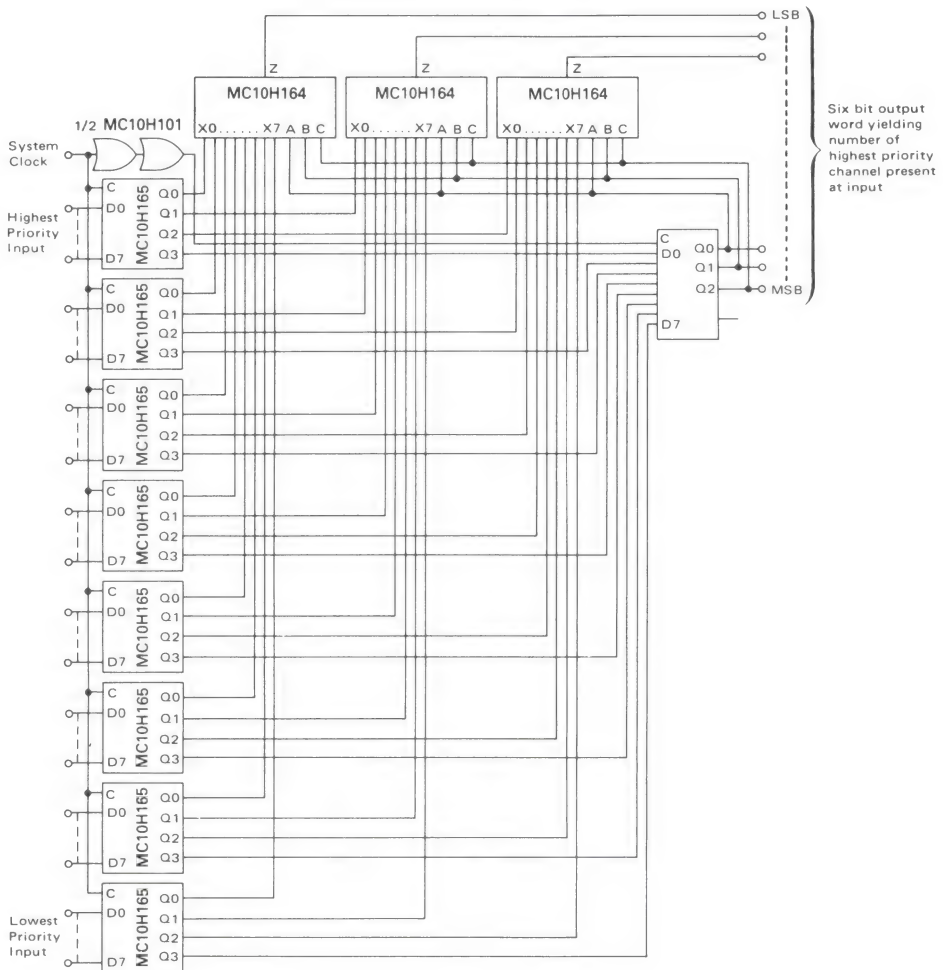

Numbers at ends of terminals denote pin numbers for L and P packages.

APPLICATION INFORMATION

A typical application of the MC10H165 is the decoding of system status on a priority basis. A 64-line priority encoder is shown in the figure below. System status lines are connected to this encoder such that, when a given condition exists, the respective input will be at a logic high level. This scheme will select the one

of 64 different system conditions, as represented at the encoder inputs, which has priority in determining the next system operation to be performed. The binary code showing the address of the highest priority input present will appear at the encoder outputs to control other system logic functions.

64-LINE PRIORITY ENCODER

MOTOROLA

MC10H166

5-BIT MAGNITUDE COMPARATOR

The MC10H166 is a 5-Bit Magnitude Comparator and is a functional/pinout duplication of the standard MECL 10K part with 100% improvement in propagation delay and no increase in power-supply current.

The MC10H166 is a high-speed expandable 5-bit comparator for comparing the magnitude of two binary words. Two outputs are provided: $A < B$ and $A > B$. The $A = B$ function can be obtained by wire-ORing these outputs (a low level indicates $A = B$) or by wire-NORing the outputs (a high level indicates $A = B$). A high level on the enable function forces both outputs low.

- Propagation Delay, Data-to-Output, 2.0 ns Typical
- Power Dissipation 440 mW Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

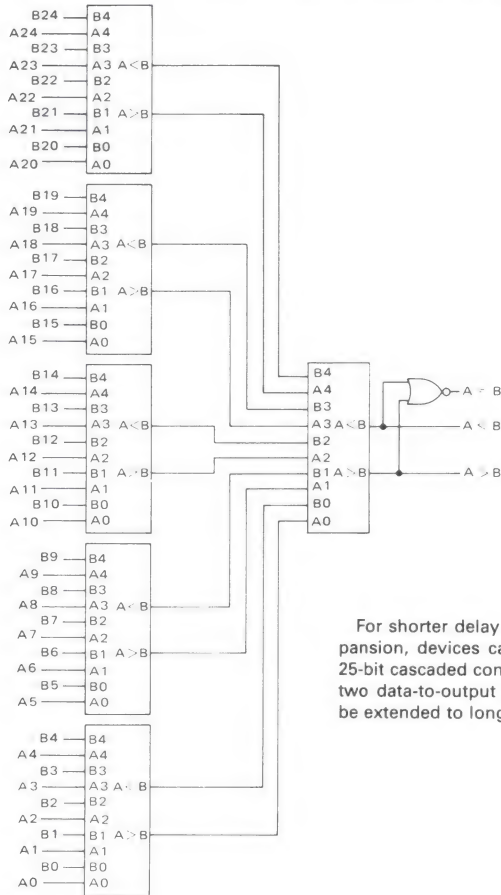

FIGURE 1 — 9-BIT MAGNITUDE COMPARATOR

For longer word lengths, the MC10H166 can be serially expanded or cascaded. Figure 1 shows two devices in a serial expansion for a 9-bit word length. The A > B and A < B outputs are fed to the A0 and B0 inputs

respectively of the next device. The connection for an A = B output is also shown. The worst case delay time of serial expansion is equal to the number of comparators times the data-to-output delay.

FIGURE 2 — 25-BIT MAGNITUDE COMPARATOR

For shorter delay times than possible with serial expansion, devices can be cascaded. Figure 2 shows a 25-bit cascaded comparator whose worst case delay is two data-to-output delays. The cascaded scheme can be extended to longer word lengths.

MOTOROLA

DUAL BINARY TO 1-4-DECODER (LOW)

The MC10H171 is a binary coded 2 line to dual 4 line decoder with selected outputs low. With either $\bar{E}0$ or $\bar{E}1$ high, the corresponding selected 4 outputs are high. The common enable E , when high, forces all outputs high.

- Propagation Delay, 2 ns Typical
- Power Dissipation 325 mW Typical (same as MECL 10K)
- Improved Noise Margin 150 mV (over operating voltage and temperature range)
- Voltage Compensated
- MECL 10K-Compatible

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

APPLICATION INFORMATION

The MC10173 is a quad two-channel multiplexer with latch. It incorporates common clock and common data select inputs. The select input determines which data input is enabled. A high (H) level enables data inputs D00, D10, D20, and D30 and a low (L) level enables data inputs D01, D11, D21, D31. Any change on the data input

will be reflected at the outputs while the clock is low. The outputs are latched on the positive transition of the clock. While the clock is in the high state, a change in the information present at the data inputs will not affect the output information.

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

APPLICATION INFORMATION

The MC10H175 is a high speed, low power quint latch. It features five D type latches with common reset and a common two-input clock. Data is transferred on the negative edge of the clock and latched on the positive edge. The two clock inputs are "OR"ed together.

Any change on the data input will be reflected at the

outputs while the clock is low. The outputs are latched on the positive transition of the clock. While the clock is in the high state, a change in the information present at the data inputs will not affect the output information. The reset input is enabled only when the clock is in the high state.

MC10H179

LOOK-AHEAD CARRY BLOCK

The MC10H179 is a functional/pinout duplication of the standard MECL 10K part, with 100% improvement in propagation delay and no increase in power supply current.

- Power Dissipation, 300 mW Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

NOTE:

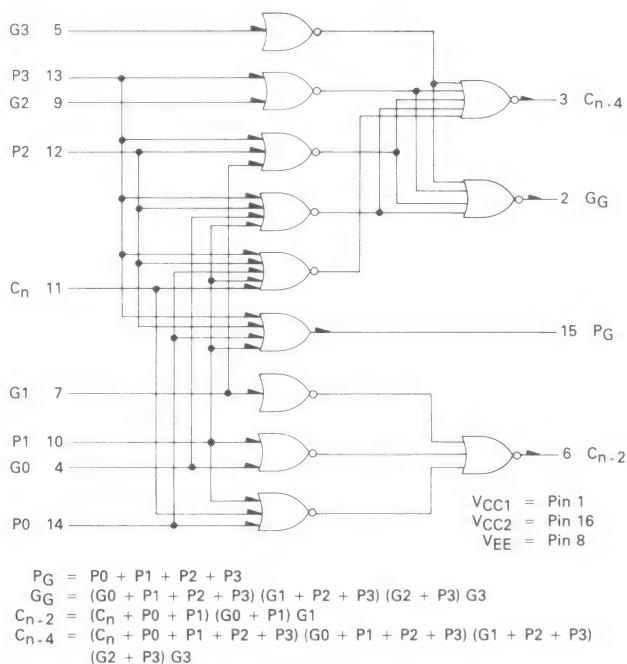

Each MECL 10KH series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 lfpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts.

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

LOGIC DIAGRAM

TYPICAL APPLICATIONS

The MC10H179 is a high-speed, low-power, standard MECL complex function that is designed to perform the look-ahead carry function. This device can be used with the MC10H181 4-bit ALU directly, or with the MC10H180 dual arithmetic unit in any computer, instrumentation or digital communication application requiring high speed arithmetic operation on long words.

When used with the MC10H181, the MC10H179 performs a second order or higher look-ahead. Figure 2 shows

a 16-bit look-ahead carry arithmetic unit. Second order carry is valuable for longer binary words. As an example, addition of two 32-bit words is improved from 30 nanoseconds with ripple-carry techniques. A block diagram of a 32-bit ALU is shown in Figure 1. The MC10H179 may also be used in many other applications. It can, for example, reduce system package count when used to generate functions of several variables.

FIGURE 1 — 32-BIT ALU WITH CARRY LOOK-AHEAD

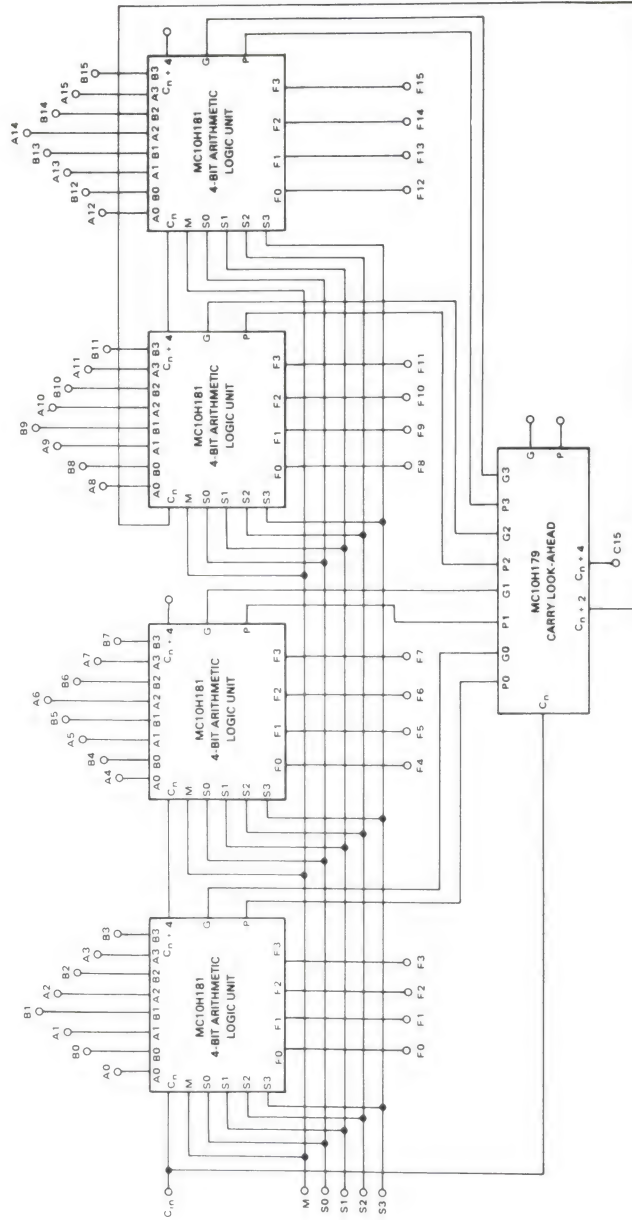

FIGURE 2 — 16-BIT FULL LOOK-AHEAD CARRY ARITHMETIC LOGIC UNIT

MOTOROLA

DUAL 2-BIT ADDER/SUBTRACTOR

The MC10H180 is a high-speed, low-power, general-purpose adder/subtractor. It is designed to be used in special purpose adders/subtractors or in high-speed multiplier arrays.

Inputs for each adder are Carry-in, Operand A, and Operand B; outputs are Sum, Sum and Carry-out. The common select inputs serve as a control line to Invert A for subtract, and a control line to Invert B.

- Propagation Delay, 1.8 ns Typical, Operand and Select to Output
- Power Dissipation, 360 mW Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

MOTOROLA

4-BIT ARITHMETIC LOGIC UNIT/ FUNCTION GENERATOR

The MC10H181 is a high-speed arithmetic logic unit capable of performing 16 logic operations and 16 arithmetic operations on two four-bit words. Full internal carry is incorporated for ripple through operation.

Arithmetic logic operations are selected by applying the appropriate binary word to the select inputs (S0 through S3) as indicated in the tables of arithmetic/logic functions. Group carry propagate (PG) and carry generate (GG) are provided to allow fast operations on very long words using a second order look-ahead. The internal carry is enabled by applying a low level voltage to the mode control input (M).

When used with the MC10H179, full-carry look-ahead, as a second order look-ahead block, the MC10H181 provides high-speed arithmetic operations on very long words.

This 10KH part is a functional/pinout duplication of the standard MECL 10K family part with 100% improvement in propagation delay and no increase in power supply current.

- Improved Noise Margin, 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K - Compatible

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

APPLICATION INFORMATION

The MC10H186 contains six high-speed, master slave type "D" flip-flops. Data is entered into the master when the clock is low. Master-to-slave data transfer takes place on the positive-going Clock transition. Thus outputs may change only on a positive-going Clock tran-

sition. A change in the information present at the data (D) input will not affect the output information any other time due to the master-slave construction of this device. A common Reset is included in this circuit. The Reset only functions when the clock is low.

LOGIC DIAGRAM

V_{CC} = Pin 16
 V_{EE} = Pin 8

MOTOROLA

HEX BUFFER WITH ENABLE

The MC10H188 is a high-speed Hex Buffer with a common Enable input. When Enable is in the high-state, all outputs are in the low-state. When Enable is in the low-state, the outputs take the same state as the inputs.

This MECL 10KH part is a functional/pinout duplication of the standard MECL 10K family part, with 100% improvement in propagation delay and no increase in power-supply current.

For PLCC pin assignment, see tables on page 1-31.

MC10H189

HEX INVERTER WITH ENABLE

The MC10H189 is a Hex Inverter with a common Enable input. The hex inverting function is provided when Enable is in the low-state. When Enable is in the high-state, all outputs are low.

This MECL 10KH part is a functional/pinout duplication of the standard MECL 10K family part, with 100% improvement in propagation delay and no increase in power-supply current.

- Propagation Delay, 1.3 ns Typical Data-to-Output
- Power Dissipation 180 mW Typ/Pkg (No Load)
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

MOTOROLA

Advance Information

DUAL 4-BIT PARITY CHECKER PLUS 2-BIT EXCLUSIVE OR GATE

The MC10H301 produces a fast, dual, 4-bit parity checker plus a 2-bit exclusive OR gate. This device is primarily used in parity checking, parity generation and error detection and correction circuits. For example, in mainframe and add-on memory systems, a 64-bit Error Detection and Correction Unit (EDCU) can be designed by using 4-MC10905's (16-bit EDCU) and 3-MC10H301's. The H301's are used in generating the syndrome and check bits (See MC10905 data sheet).

- Propagation Delay, 1.5 ns Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

MOTOROLA

Advance Information

8-BIT/DUAL 4-BIT PARITY CHECKER

The MC10H304 produces a fast, 8-bit parity checker including a 4-bit parity check on each of the two 4-bit nibbles. This device is primarily used in parity checking, parity generation, and error detection and correction circuits. For example, in mainframe and add-on memory systems, a 96-bit Error Detection and Correction Unit (EDCU) can be designed by using 7-MC10905's (16-bit EDCU) and 6-MC10H304's and 1-MC10H301. The H301 is used in generating the syndrome and check bits (See MC10905 data sheet).

- Propagation Delay, 1.5 ns Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

MOTOROLA

QUAD BUS DRIVER/RECEIVER WITH 2-TO-1 OUTPUT MULTIPLEXERS

The MC10H330 is a Quad Bus Driver/Receiver with two-to-one output multiplexers. These multiplexers have a common select and output enable. When disabled, ($\overline{OE} = \text{high}$) the bus outputs go to -2.0 V. Their output can be brought to a low state (V_{OL}) by applying a high level to the receiver enable ($\overline{RE} = \text{High}$). The parameters specified are with $25\ \Omega$ loading on the bus drivers and $50\ \Omega$ loads on the receivers.

- Propagation Delay, 1.5 ns Typical Data-to-Output
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K-Compatible

MC10H350

ECL TO TTL TRANSLATOR (+ 5 Vdc Power Supply Only)

The MC10H350 is a member of Motorola's 10KH family of high performance ECL logic. It consists of 4 translators with differential inputs and TTL outputs. The 3-state outputs can be disabled by applying a HIGH TTL logic level on the common OE input.

The MC10H350 is designed to be used primarily in systems incorporating both ECL and TTL logic operating off a common power supply. The separate V_{CC} power pins are not connected internally and thus isolate the noisy TTL V_{CC} runs from the relatively quiet ECL V_{CC} runs on the printed circuit board. The differential inputs allow the H350 to be used as an inverting or noninverting translator, a differential line receiver or as a high performance comparator.

- Propagation Delay, 3.5 ns Typical
- MECL 10K-Compatible

Product Preview

QUAD TTL/NMOS TO MECL TRANSLATOR

The MC10H351 is a quad translator for interfacing data between a saturated logic section and the MECL section of digital systems when only a +5.0 Vdc power supply is available. The MC10H351 has TTL/NMOS compatible inputs and MECL complementary open-emitter outputs that allow use as an inverting/non-inverting translator or as a differential line driver. When the common strobe input is at a low logic level, it forces all true outputs to the MECL low logic state ($\approx +3.2$ V) and all inverting outputs to the MECL high logic state ($\approx +4.1$ V).

The MC10H351 can also be used with the MC10H350 to transmit and receive TTL/NMOS information differentially via balanced twisted pair lines.

- Single +5.0 V Power Supply
- All V_{CC} Pins Isolated On Chip
- Differentially Drive Balanced Lines
- $t_{pd} = 1.3$ nsec Typical

MC10H351

AC PARAMETERS

Characteristic	Symbol	0°		25°		75°		Unit
		Min	Max	Min	Max	Min	Max	
Propagation Delay (1)	t_{pd}	0.4	1.9	0.4	2.0	0.4	2.1	ns
Rise Time (20% to 80%)	t_r	0.4	1.9	0.4	2.0	0.4	2.1	ns
Fall Time (80% to 20%)	t_f	0.4	1.9	0.4	2.0	0.4	2.1	ns
Maximum Operating Frequency	f_{max}	150	—	150	—	150	—	MHz

(1) Propagation delay is measured on this circuit from +1.5 volts on the input waveform to the 50% point on the output waveform.

NOTE:

Each MECL 10KH series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 lfpm is maintained. Outputs are terminated through a 50-ohm resistor to $V_{CC} - 2.0$ Vdc.

QUAD CMOS TO MECL TRANSLATOR

The MC10H352 is a quad translator for interfacing data between a CMOS logic section and the MECL section of digital systems when only a +5.0 Vdc power supply is available. The MC10H352 has CMOS compatible inputs and MECL complementary open-emitter outputs that allow use as an inverting/non-inverting translator or as a differential line driver. When the common strobe input is at a low logic level, it forces all true outputs to the MECL low logic state ($\approx +3.2$ V) and all inverting outputs to the MECL high logic state ($\approx +4.1$ V).

The MC10H352 can also be used with the MC10H350 to transmit and receive CMOS information differentially via balanced twisted pair lines.

- Single +5.0 V Power Supply
- All V_{CC} Pins Isolated On Chip
- Differentially Drive Balanced Lines
- $t_{pd} = 1.3$ nsec Typical

MAXIMUM RATINGS

Outputs are terminated through a 50-ohm resistor to $V_{CC} - 2.0$ Vdc.

MOTOROLA

MC10H423

TRIPLE-3 INPUT BUS DRIVER WITH ENABLE

The MC10H423 is a triple 3 Input Bus Driver with a common enable.

The MC10H423 consists of three NOR gates designed for bus driving applications on card or between cards. Output low logic levels are specified with $V_{OL} = -2.1 \text{ Vdc}$ so that the bus may be terminated to -2.0 Vdc . The gate output, when low, appears as a high impedance to the bus, because the output emitter-followers of the MC10H423 are "turned off." This eliminates discontinuities in the characteristic impedance of the bus.

The V_{OH} level is specified when driving a 25-ohm load terminated to -2.0 Vdc , the equivalent of a 50-ohm bus terminated at both ends. Although 25 ohms is the lowest characteristic impedance that can be driven by the MC10H423, higher impedance values may be used with this part. A typical 50 ohm bus is shown in Figure 1.

- Propagation Delay, 1.5 ns Typical
- Voltage Compensated
- Improved Noise Margin 150 mV (Over
- MECL 10K-Compatible Operating Voltage and Temperature Range)

FIGURE 1 — 50-OHM BUS DRIVER (25-OHM LOAD)

The diagram illustrates a 50-ohm bus driver circuit. It features three MC10H423 gates, each labeled $1/3$ MC10H423. The gates are configured as inverters, with their inputs and outputs connected to a central 50-ohm bus. The bus is terminated at both ends with 50-ohm resistors connected to -2.0 Vdc. The bus is labeled $Z_0 = 50\Omega$. The receivers are labeled RECEIVERS (MECL Gates).

MOTOROLA

MC10H424

QUAD TTL-TO-ECL TRANSLATOR WITH AN ECL STROBE

The MC10H424 is a Quad TTL-to-ECL translator with an ECL strobe. Power supply requirements are ground, +5.0 volts, and -5.2 volts.

- Propagation Delay, 1.5 ns Typical
- Improved Noise Margin 150 mV (Over Operating Voltage and Temperature Range)
- Voltage Compensated
- MECL 10K — Compatible

NOTE:

Each MECL 10KH series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 lfpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts.

APPLICATIONS INFORMATION

The MC10H424 has TTL-compatible inputs, an ECL strobe and MECL complementary open-emitter outputs that allow use as an inverting/non-inverting translator or as a differential line driver. When the common strobe input is at the low-logic level, it forces all true outputs to a MECL low-logic state and all inverting

outputs to a MECL high-logic state.

An advantage of this device is that TTL-level information can be transmitted differentially, via balanced twisted pair lines, to MECL equipment, where the signal can be received by the MC10H115 or MC10H116 differential line receivers.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one input and one output. The other inputs and outputs are tested in the same manner.

*Individually test each input applying V_{IH} or V_{IL} to input under test.

MOTOROLA

MC10101

QUAD OR/NOR GATE

The MC10101 is a quad 2-input OR/NOR gate with one input from each gate common to pin 12.

$P_D = 25 \text{ mW typ/gate (No Load)}$

$t_{pd} = 2.0 \text{ ns typ}$

$t_r, t_f = 2.0 \text{ ns typ (20\%--80\%)}$

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one gate. The other gates are tested in the same manner.

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one gate. The other gates are tested in the same manner.

MOTOROLA

MC10110

**DUAL 3-INPUT 3-OUTPUT
"OR" GATE**

The MC10110 is designed to drive up to three transmission lines simultaneously. The multiple outputs of this device also allow the wire "OR" ing of several levels of gating for minimization of gate and package count.

The ability to control three parallel lines from a single point makes the MC10110 particularly useful in clock distribution applications where minimum clock skew is desired. Three V_{CC} pins are provided and each one should be used.

P_D = 80 mW typ/gate (No Load)
 t_{pd} = 2.4 ns typ (All Outputs Loaded)
 t_r, t_f = 2.2 ns typ (20%–80%)

MC10114

MECL 10K SERIES

TRIPLE LINE RECEIVER

TRIPLE LINE RECEIVER

The MC10114 is a triple line receiver designed for use in sensing differential signals over long lines. An active current source and translated emitter follower inputs provide the line receiver with a common mode noise rejection limit of one volt in either the positive or the negative direction. This allows a large amount of common mode noise immunity for extra long lines.

Another feature of the MC10114 is that the OR outputs go to a logic low level whenever the inputs are left floating. The outputs are each capable of driving 50 ohm transmission lines.

This device is useful in high speed central processors, mini-computers, peripheral controllers, digital communication systems, testing and instrumentation systems. The MC10114 can also be used for MOS to MECL interfacing and it is ideal as a sense amplifier for MOS RAM's.

A V_{BB} reference is provided which is useful in making the MC10114 a Schmitt trigger, allowing single-ended driving of the inputs, or other applications where a stable reference voltage is necessary. See MECL Design Handbook (HB205) pages 226 and 228.

P_D = 145 mW typ/pkg
 t_{pd} = 2.4 ns typ (Single Ended Input)
 t_{pd} = 2.0 ns typ (Differential Input)
 t_r, t_f = 2.1 ns typ (20% to 80%)

LOGIC DIAGRAM

V_{CC1} = Pin 1
 V_{CC2} = Pin 16

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
 For PLCC pin assignment, see tables on page 1-31.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one gate. The other gates are tested in the same manner.

MOTOROLA

MC10115

QUAD LINE RECEIVER

The MC10115 is a quad differential amplifier designed for use in sensing differential signals over long lines. The base bias supply (V_{BB}) is made available at pin 9 to make the device useful as a Schmitt trigger, or in other applications where a stable reference voltage is necessary.

Active current sources provide the MC10115 with excellent common mode noise rejection. If any amplifier in a package is not used, one input of that amplifier must be connected to V_{BB} (pin 9) to prevent upsetting the current source bias network.

$$P_D = 110 \text{ mW typ/pkg (No Load)}$$

$$t_{pd} = 2.0 \text{ ns typ}$$

$$t_r, t_f = 2.0 \text{ ns typ (20\%--80\%)}$$

When the input pin with the bubble goes positive, the output goes negative.

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one gate. The other gates are tested in the same manner.

MOTOROLA

MC10116

MECL 10K SERIES

TRIPLE LINE RECEIVER

The MC10116 is a triple differential amplifier designed for use in sensing differential signals over long lines. The base bias supply (V_{BB}) is made available at pin 11 to make the device useful as a Schmitt trigger, or in other applications where a stable reference voltage is necessary.

Active current sources provide the MC10116 with excellent common mode noise rejection. If any amplifier in a package is not used, one input of that amplifier must be connected to V_{BB} (pin 11) to prevent upsetting the current source bias network.

Complementary outputs are provided to allow driving twisted pair lines, to enable cascading of several amplifiers in a chain, or simply to provide complement outputs of the input logic function.

$$P_D = 85 \text{ mW typ/pkg (No Load)}$$

$$t_{pd} = 2.0 \text{ ns typ}$$

$$t_r, t_f = 2.0 \text{ ns typ (20\%-80\%)}$$

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one gate. The other gates are tested in the same manner.

MOTOROLA

MC10123

TRIPLE 4-3-3 INPUT BUS DRIVER

The MC10123 consists of three NOR gates designed for bus driving applications on card or between cards. Output low logic levels are specified with $V_{OL} = -2.1$ Vdc so that the bus may be terminated to -2.0 Vdc. The gate output, when low, appears as a high impedance to the bus, because the output emitter-followers of the MC10123 are "turned-off." This eliminates discontinuities in the characteristic impedance of the bus.

The V_{OH} level is specified when driving a 25-ohm load terminated to -2.0 Vdc, the equivalent of a 50-ohm bus terminated at both ends. Although 25 ohms is the lowest characteristic impedance that can be driven by the MC10123, higher impedance values may be used with this part. A typical 50-ohm bus is shown in Figure 1.

$P_D = 310$ mW typ/pkg (No Load)
 $t_{pd} = 3.0$ ns typ
 $t_r, t_f = 2.5$ ns typ (20%–80%)

MOTOROLA

MC10124

QUAD TTL TO MECL TRANSLATOR

The MC10124 is a quad translator for interfacing data and control signals between a saturated logic section and the MECL section of digital systems. The MC10124 has TTL compatible inputs, and MECL complementary open-emitter outputs that allow use as an inverting/non-inverting translator or as a differential line driver. When the common strobe input is at the low logic level, it forces all true outputs to a MECL low logic state and all inverting outputs to a MECL high logic state.

Power supply requirements are ground, +5.0 Volts, and -5.2 Volts. Propagation delay of the MC10124 is typically 3.5 ns. The dc levels are standard or Schottky TTL in, MECL 10,000 out.

An advantage of this device is that TTL level information can be transmitted differentially, via balanced twisted pair lines, to the MECL equipment, where the signal can be received by the MC10115 or MC10116 differential line receivers. The MC10124 is useful in computers, instrumentation, peripheral controllers, test equipment, and digital communications systems.

P_D	= 380 mW typ/pkg (No Load)
t_{pd}	= 3.5 ns typ (+ 1.5 Vdc in to 50% out)
t_r, t_f	= 2.5 ns typ (20%–80%)

SWITCHING TIME TEST CIRCUIT

MOTOROLA

MC10125

QUAD MECL TO TTL TRANSLATOR

The MC10125 is a quad translator for interfacing data and control signals between the MECL section and saturated logic sections of digital systems. The MC10125 incorporates differential inputs and Schottky TTL "totem pole" outputs. Differential inputs allow for use as an inverting/non-inverting translator or as a differential line receiver. The V_{BB} reference voltage is available on pin 1 for use in single-ended input biasing. The outputs of the MC10125 go to a low logic level whenever the inputs are left floating.

Power supply requirements are ground, +5.0 Volts and -5.2 Volts. Propagation delay of the MC10125 is typically 4.5 ns. The MC10125 has fanout of 10 TTL loads. The dc levels are MECL 10,000 in and Schottky TTL, or TTL out. This device has an input common mode noise rejection of ± 1.0 Volt.

An advantage of this device is that MECL level information can be received, via balanced twisted pair lines, in the TTL equipment. This isolates the MECL logic from the noisy TTL environment. This device is useful in computers, instrumentation, peripheral controllers, test equipment and digital communications systems.

P_D = 380 mW typ/pkg (No Load)
 t_{pd} = 4.5 ns typ (50% to + 1.5 Vdc out)
 t_r, t_f = 2.5 ns typ (1.0 V to 2.0 V)

① Individually test each input, apply $V_{IH\ max}$ to pin under test.

SWITCHING TIME TEST CIRCUIT

MOTOROLA

MC10128

BUS DRIVER

The MC10128 is designed to provide outputs which are compatible with IBM-type bus levels; or, if desired, it will drive TTL type loads and/or provide TTL three-state outputs. The inputs accept MECL 10,000 levels. The MC10128 output levels can be accepted by the MC10129 Bus Receiver.

The operating mode IBM or TTL is selected by tying the external control pins to ground or leaving them open. Leaving a control pin open selects the TTL mode, and tying a control pin to ground selects the IBM mode.

The TTL mode will drive a 25-ohm load, terminated to +1.5 Vdc or a 50-ohm load, terminated to ground. The device has totem-pole type outputs, but it also has a disable input for three-state logic operation when the circuit is used in the TTL mode. When in the high state the disable input causes the output to exhibit a high impedance state when it would normally be a positive logic "1" state. When the strobe is in the high state it inhibits the output data in the low state.

Latches are provided on each data input for temporary storage. When the clock input is in the low logic state, information present at the data inputs D1 and D2 will be fed directly to the latch output. When the clock goes high, the input data is latched. The outputs are gated to allow full bus driving and strobing capability.

The MC10128 is useful in interfacing and bus applications in central processors, mini-computers, and peripheral equipment.

MOTOROLA

QUAD BUS RECEIVER

The MC10129 bus receiver works in conjunction with the MC10128 to allow interfacing of MECL 10,000 to other forms of logic and logic buses. The data inputs are compatible with, and accept TTL logic levels as well as levels compatible with IBM-type buses. The clock, strobe, and reset inputs accept MECL 10,000 logic levels.

The data inputs accept the bus levels, and storage elements are provided to yield temporary latch storage of the information after receiving it from the bus. The outputs can be strobed to allow accurate synchronization of signals and/or connection to MECL 10,000 level buses. When the clock is low, the outputs will follow the D inputs, and the reset input is disabled. The latches will store the data on the rising edge of the clock. The outputs are enabled when the strobe input is high. Unused D inputs must be tied to VCC or Gnd. The clock, strobe, and reset inputs each have 50 k ohm pulldown resistors to VEE. They may be left floating, if not used.

The MC10129 will operate in either of two modes. The first mode is obtained by tying the hysteresis control input to VEE. In this mode, the input threshold points of the D inputs are fixed. The second mode is obtained by tying the hysteresis control input to ground. In this mode, input hysteresis is achieved as shown in the test table. This hysteresis is desirable where extra noise margin is required on the D inputs. The output pins are unaffected by the mode of operation used.

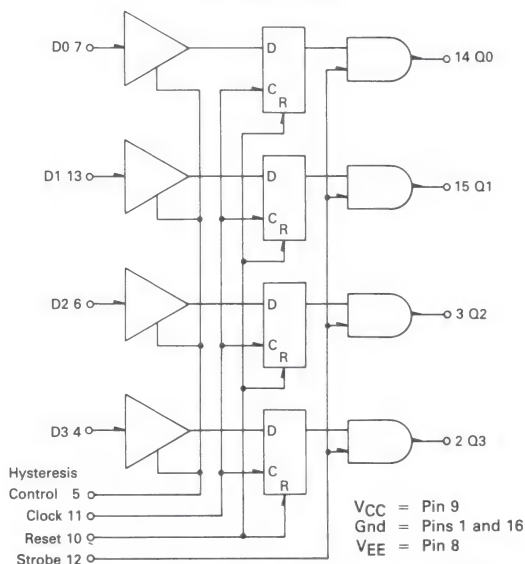

The MC10129 is especially useful in interface applications for central processors, mini-computers, and peripheral equipment.

MC10130

DUAL LATCH

The MC10130 is a clocked dual D type latch. Each latch may be clocked separately by holding the common clock in the low state, and using the clock enable inputs for the clocking function. If the common clock is to be used to clock the latch, the clock enable (\overline{CE}) inputs must be in the low state. In this mode, the enable inputs perform the function of controlling the common clock (\overline{C}).

Any change at the D input will be reflected at the output while the clock is low. The outputs are latched on the positive transition of the clock. While the clock is in the high state, a change in the information present at the data inputs will not affect the output information.

The set and reset inputs do not override the clock and D inputs. They are effective only when either \overline{C} or CE or both are high.

$$P_D = 155 \text{ mW typ/pkg (No Load)}$$

MOTOROLA

MC10131

**DUAL TYPE D MASTER-SLAVE
FLIP-FLOP**

The MC10131 is a dual master-slave type D flip-flop. Asynchronous Set (S) and Reset (R) override Clock (C_C) and $\overline{\text{Clock Enable}}$ ($\overline{C_E}$) inputs. Each flip-flop may be clocked separately by holding the common clock in the low state and using the enable inputs for the clocking function. If the common clock is to be used to clock the flip-flop, the Clock Enable inputs must be in the low state. In this case, the enable inputs perform the function of controlling the common clock.

The output states of the flip-flop change on the positive transition of the clock. A change in the information present at the data (D) input will not affect the output information at any other time due to master slave construction.

MOTOROLA

MC10132

**DUAL MULTIPLEXER WITH
LATCH AND COMMON RESET**

The MC10132 is a dual multiplexer with clocked D type latches. It incorporates common data select and reset inputs. Each latch may be clocked separately by holding the common clock in the low state, and using the clock enable inputs for a clocking function. If the common clock is to be used to clock the latch, the clock enable (\overline{CE}) inputs must be in the low state. In this mode, the enable inputs perform the function of controlling the common clock (C_C).

The data select (A) input determines which data input is enabled. A high (H) level enables data inputs D12 and D22 and a low (L) level enables data inputs D11 and D21. Any change on the data input will be reflected at the outputs while the clock is low. The outputs are latched on the positive transition of the clock. While the clock is in the high state, a change in the information present at the data inputs will not affect the output information. The reset input is enabled when the clock is in the high state, and disabled when the clock is low.

$P_D = 225 \text{ mW typ/pkg (No Load)}$

$t_{pd} = 3.0 \text{ ns typ}$

$t_r, t_f = 2.5 \text{ ns typ (20\%–80\%)}$

PIN ASSIGNMENT

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -20 volts. Test procedures are shown for only one latch. The other latches are tested in the same manner.

- All other inputs tested in the same manner.

MOTOROLA

MC10133

QUAD LATCH

The MC10133 is a high speed, low power, quad latch consisting of four bistable latch circuits with D type inputs and gated Q outputs, allowing direct wiring to a bus. When the clock is high, outputs will follow D inputs. Information is latched on the negative going transition of the clock.

The outputs are gated when the output enable (\overline{G}) is low. All four latches may be clocked at one time with the common clock (C_C), or each half may be clocked separately with its clock enable ($\overline{C_E}$).

MOTOROLA

MC10135

**DUAL J-K MASTER-SLAVE
FLIP-FLOP**

The MC10135 is a dual master-slave dc coupled J-K flip-flop. Asynchronous set (S) and reset (R) are provided. The set and reset inputs override the clock.

A common clock is provided with separate \bar{J} - \bar{K} inputs. When the clock is static, the \bar{J} - \bar{K} inputs do not effect the output.

The output states of the flip-flop change on the positive transition of the clock.

- ② Individually test each input; apply V_{IL} min to pin under test.
- ③ Output level to be measured after a clock pulse has been applied to the C input (pin 9).
- ④ Output level to be measured after a clock pulse has been applied to the C input (pin 9).
- ⑤ See Figure 2 for timing test diagram.

MOTOROLA

MC10136

UNIVERSAL HEXADECIMAL COUNTER

The MC10136 is a high speed synchronous counter that can count up, count down, preset, or stop count at frequencies exceeding 100 MHz. The flexibility of this device allows the designer to use one basic counter for most applications, and the synchronous count feature makes the MC10136 suitable for either computers or instrumentation.

Three control lines (S1, S2, and Carry In) determine the operation mode of the counter. Lines S1 and S2 determine one of four operations; preset (program), increment (count up), decrement (count down), or hold (stop count). Note that in the preset mode a clock pulse is necessary to load the counter, and the information present on the data inputs (D0, D1, D2, and D3) will be entered into the counter. Carry Out goes low on the terminal count, or when the counter is being preset.

This device is not designed for use with gated clocks. Control is via S1 and S2.

$P_D = 625 \text{ mW typ/pkg (No Load)}$
 $f_{\text{count}} = 150 \text{ MHz typ}$
 $t_{pd} = 3.3 \text{ ns typ (C-Q)}$
 $7.0 \text{ ns typ (C-C}_{\text{out}})$
 $5.0 \text{ ns typ (C}_{\text{in}}\text{-C}_{\text{out}})$

* Truth table shows logic states assuming inputs vary in sequence shown from top to bottom.

** A clock H is defined as a clock input transition from a low to a high logic level.

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Test procedures are shown for only one output. The other outputs are tested in the same manner.

[illegible]

To preserve reliable performance, the MC10136 (plastic-packaged device only) is to be operated in ambient temperatures above 70°C only when 500 lpm blown air or equivalent heat sinking is provided.

① Individually apply V_{II} min to pin under test

③ Before test set all Q outputs to a logic high

SWITCHING TIME TEST CIRCUIT AND WAVEFORMS @ 25°C

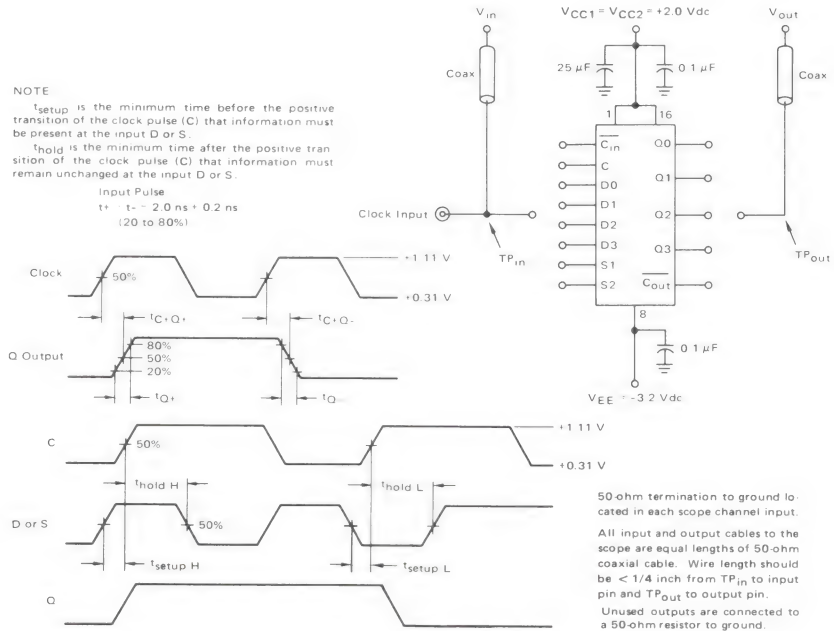

NOTE

t_{setup} is the minimum time before the positive transition of the clock pulse (C) that information must be present at the input D or S.

t_{hold} is the minimum time after the positive transition of the clock pulse (C) that information must remain unchanged at the input D or S.

Input Pulse

$$t^+ - t^- = 2.0 \text{ ns} \pm 0.2 \text{ ns} \\ (20 \text{ to } 80\%)$$

CARRY IN SET UP AND HOLD TIMES

APPLICATIONS INFORMATION

To provide more than four bits of counting capability several MC10136 counters may be cascaded. The $\overline{\text{Carry In}}$ input overrides the clock when the counter is either in the increment mode or the decrement mode of operation. This input allows several devices to be cascaded in a fully synchronous multistage counter as illustrated in Figure 1. The carry is advanced between stages as shown with no external gating. The $\overline{\text{Carry In}}$ of the first device may be left open. The system clock is common to all devices.

The various operational modes of the counter make it useful for a wide variety of applications. If used with MECL III devices, prescalers with input toggle frequencies in excess of 300 MHz are possible. Figure 2 shows such a prescaler using the MC10136 and MC1670. Use of the MC10231 in place of the MC1670 permits 200 MHz operation.

The MC10136 may also be used as a programmable counter. The configuration of Figure 3 requires no additional gates, although maximum frequency is limited to about 50 MHz. The divider modulus is equal to the program input plus one ($M = N + 1$), therefore, the counter will divide by a modulus varying from 1 to 16.

A second programmable configuration is also illustrated in Figure 4. A pulse swallowing technique is used to speed the counter operation up to 110 MHz typically. The divider modulus for this figure is equal to the program input ($M = N$). The minimum modulus is 2 because of the pulse swallowing technique, and the modulus may vary from 2 to 15. This programmable configuration requires an additional gate, such as $\frac{1}{2}$ MC10109 and a flip-flop such as $\frac{1}{2}$ MC10131.

MOTOROLA

MC10137

UNIVERSAL DECADE COUNTER

The MC10137 is a high speed synchronous counter that can count up, down, preset, or stop count at frequencies exceeding 100 MHz. The flexibility of this device allows the designer to use one basic counter for most applications. The synchronous count feature makes the MC10137 suitable for either computers or instrumentation.

Three control lines (S1, S2, and Carry In) determine the operation mode of the counter. Lines S1 and S2 determine one of four operations; preset (program), increment (count up), decrement (count down), or hold (stop count). Note that in the preset mode a clock pulse is necessary to load the counter, and the information present on the data inputs (D0, D1, D2, and D3) will be entered into the counter. Carry Out goes low on the terminal count. The Carry Out on the MC10137 is partially decoded from Q1 and Q2 directly, so in the preset mode the condition of the Carry Out after the Clock's positive excursion will depend on the condition of Q1 and/or Q2. The counter changes state only on the positive going edge of the clock. Any other input may change at any time except during the positive transition of the clock. The sequence for counting out of improper states is as shown in the State Diagrams.

$P_D = 625 \text{ mW typ/pkg (No Load)}$
 $f_{\text{count}} = 150 \text{ MHz typ}$
 $t_{pd} = 3.3 \text{ ns typ (C-Q)}$
 $= 7.0 \text{ ns typ (C-C}_{out})$
 $= 5.0 \text{ ns typ (C}_{in}\text{-C}_{out})$

* Individually apply V_{ILmin} to pin under test.

① Set all four flip-flops by applying pulse V_{IHmax} to pins 5,6,10,11 prior to applying test voltage indicated.

② Reset all four flip-flops by applying pulse V_{ILmin} to pin 9 prior to applying test voltage indicated.

MC10141

FOUR-BIT UNIVERSAL SHIFT REGISTER

The MC10141 is a four-bit universal shift register which performs shift left, or shift right, serial/parallel in, and serial/parallel out operations with no external gating. Inputs S1 and S2 control the four possible operations of the register without external gating of the clock. The flip-flops shift information on the positive edge of the clock. The four operations are stop shift, shift left, shift right, and parallel entry of data. The other six inputs are all data type inputs; four for parallel entry data, and one for shifting in from the left (DL) and one for shifting in from the right (DR).

$P_D = 425 \text{ mW typ/pkg (No Load)}$
 $f_{\text{Shift}} = 200 \text{ MHz typ}$
 $t_r, t_f = 2.0 \text{ ns typ (20\%--80\%)}$

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
 For PLCC pin assignment, see tables on page 1-31.

SHIFT FREQUENCY TEST CIRCUIT

All input and output cables to the scope are equal lengths of 50-ohm coaxial cable. Wire length should be $< 1/4$ inch from TP_{in} to input pin and TP_{out} to output pin.

Test Procedures:

1. Set D1, D2, D3 = +0.31 Vdc (Logic L)
D0 = +1.11 Vdc (Logic H)
2. Apply Clock pulse $\begin{matrix} V_{IH} \\ \text{---} \\ V_{IL} \end{matrix}$ to set Q0 high.
3. Maintain Clock Low.
Set S1 = +0.31 Vdc (Logic L)
S2 = +1.11 Vdc (Logic H)
4. Test Shift Frequency

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established in an ambient temperature of 25°C, while the circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one input, or for one set of input conditions. Other inputs tested in the same manner.

 ④ Reset to zero before performing test.
 ⑤ Reset to one before performing test.

MOTOROLA

MC10153

QUAD LATCH

The MC10153 is a high speed, low power, MECL quad latch consisting of four bistable latch circuits with D type inputs and gated Q outputs. Open emitters allow a large number of outputs to be wire-ORed together. Latch outputs are gated, allowing direct wiring to a bus. When the clock is low, outputs will follow D inputs. Information is latched on positive going transition of the clock. The MC10153 provides the same logic function as the MC10133, except for inversion of the clock.

$P_D = 310 \text{ mW typ/pkg (No Load)}$
 $t_{pd} = 4.0 \text{ ns typ}$
 $t_r, t_f = 2.0 \text{ ns typ (20\%--80\%)}$

MC10154

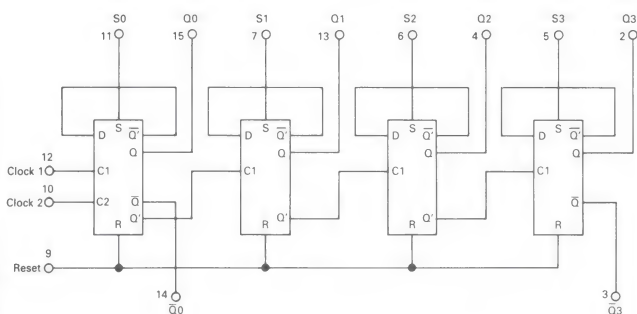

BINARY COUNTER

The MC10154 is a four-bit counter capable of divide-by-two, divide-by-four, divide-by-eight or a divide-by-sixteen function.

Clock inputs trigger on the positive going edge of the clock pulse. Set and Reset inputs override the clock, allowing asynchronous "set" or "clear." Individual Set and common Reset inputs are provided, as well as complementary outputs for the first and fourth bits. True outputs are available at all bits.

P_D = 370 mW typ/pkg (No Load)
 f_{toggle} = 150 m Hz (typ)
 t_{pd} = 3.5 ns typ (C to Q₀)
 t_{pd} = 11 ns typ (C to Q₃)

The diagram shows a 3-to-8 decoder implemented using a 74148 3-to-8 priority encoder and a 74138 3-to-8 decoder. The 74148 has inputs $\overline{E_0}$ (2), $\overline{E_1}$ (15), and A (7), and outputs Q0 (6), Q1 (5), Q2 (4), Q3 (3), Q4 (13), Q5 (12), Q6 (11), and Q7 (10). The 74138 has inputs A (9), B (9), and C (14), and outputs Q0 (6), Q1 (5), Q2 (4), Q3 (3), Q4 (13), Q5 (12), Q6 (11), and Q7 (10). The 74148's Q0-Q3 outputs are connected to the 74138's A-B-C inputs. The 74148's Q4-Q7 outputs are connected to the 74138's Q0-Q7 outputs. The 74148's $\overline{E_0}$ and $\overline{E_1}$ inputs are connected to the 74138's A and B inputs. The 74148's Q0-Q3 outputs are connected to the 74138's Q0-Q7 outputs. The 74148's Q4-Q7 outputs are connected to the 74138's Q0-Q7 outputs. The 74148's Q0-Q3 outputs are connected to the 74138's Q0-Q7 outputs. The 74148's Q4-Q7 outputs are connected to the 74138's Q0-Q7 outputs.

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one input/output combination. Other combinations are tested according to the truth table.

3-97

MOTOROLA

MC10162

BINARY TO 1-8 DECODER (HIGH)

The MC10162 is designed to convert three lines of input data to a one-of-eight output. The selected output will be high while all other outputs are low. The enable inputs, when either or both are high, force all outputs low.

The MC10162 is a true parallel decoder. No series gating is used internally, eliminating unequal delay times found in other decoders.

This device is ideally suited for demultiplexer applications. One of the two enable inputs is used as the data input, while the other is used as a data enable input.

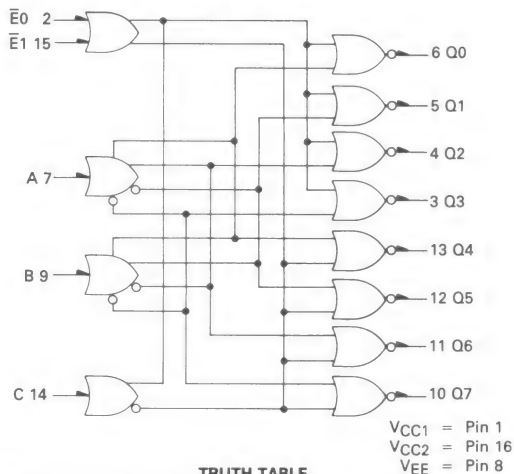

A complete mux/demux operation on 16 bits for data distribution is illustrated in Figure 1 of the MC10161 data sheet.

$P_D = 315 \text{ ns typ/pkg (No Load)}$

$t_{pd} = 4.0 \text{ ns typ}$

$t_r, t_f = 2.0 \text{ ns typ (20\%–80\%)}$

MC10193**

ERROR DETECTION- CORRECTION CIRCUIT

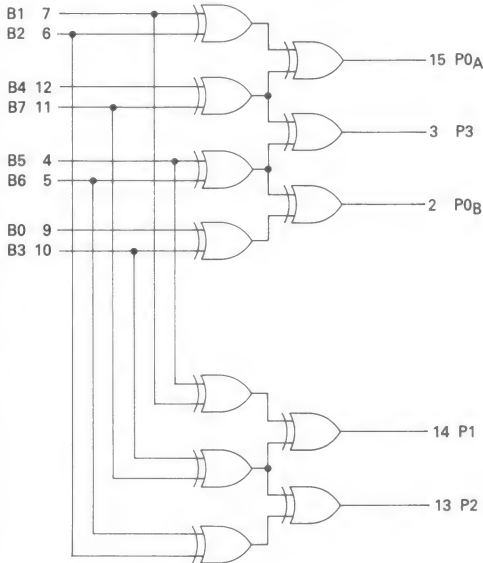

The MC10163 and the MC10193 are error detection and correction circuits. They are building blocks designed for use with memory systems. They offer economy in the design of error detection/correction subsystems for mainframe and add-on memory systems. For example, using eight MC10163s together with eight 12-bit parity checkers (MC10160), single-bit error detection/correction and double-bit error detection can be done on a word of 64-bit length. Only eight check bits (B0-B7) need be added to the word. A useful feature of this building block is that the MC10193 option generates the parity of all inputs to the block. Thus, if the MC10193 is applied in a byte sequence, individual byte parity is automatically available.

MC10163 APPLICATIONS INFORMATION

The MC10163 is a building block for generating the modified Hamming single-error-correction, double-error-detection (SEC-DED) code used in the IBM 370/145 memory. While the MC10163 can also be used for generating other patterns, it is optimized for generating the pattern shown in the H matrix of Figure 1.

When writing into a memory, the MC10163 is used to generate the eight check bits (C0–C32, CT) which are stored with the 65 data bits (B0–B63). These check bits are generated by taking the parity of all data bits marked with an X in the appropriate row of the H matrix. (C0, C1, C32, CT, are even parity; C2, C4, C8, C17, are odd parity.) To generate these check bits with the building blocks, eight MC10163s and eight MC10160 parity checkers are used. One MC10163 is connected to each byte of data and the outputs of these building blocks are connected to the eight MC10160 parity checkers, one for each check bit. Figure 2 shows which connections are required (i.e., C0 is the even parity of output P0A of the MC10163 on the "zero" byte of data, output P0B of the "zero" byte, P0A of the "one" byte, —, P0B of the "three" byte and data bit 32.)

During the memory read operation, the fetched check bits previously generated (as described) are exclusive-ORed with newly generated C0–C32 to generate syndrome bits S0–S32. Syndrome ST is a special case where ST is the even parity of all eight fetched check bits and all 64 fetched data bits. For determining the type and location of an error:

1. If all syndromes (S0–S32 and ST) are false, there is no error.
2. If ST is true and S0–S32 are false, the CT is in error.
3. If ST is false and one or more of S0–S32 is true, an uncorrectable error has occurred.
4. If ST is true and one or more of S0–S32 is true, simply add the S1–S32 bits to get the binary location of the error (S1 has weight, 1, S2 weight 2, S4 weight 4, etc.)

Data bits B0 and B32 are special cases of this location technique: B0 is in error if ST, S0, and S32 are true; B32 is in error if ST, S0, S1, and S32 are true.

APPLICATION INFORMATION

The MC10164 can be used wherever data multiplexing or parallel to serial conversion is desirable. Full parallel gating permits equal delays through any data path. The output of the MC10164 incorporates a buffer gate with

eight data inputs and an enable. A high level on the enable forces the output low. The MC10164 can be connected directly to a data bus, due to its open emitter output and output enable.

Figure one illustrates how a 1-of-64 line multiplexer can be built with eight MC10164's wire ORed at their outputs and one MC10161 to drive the enables on each multiplexer, without speed degradation over a single MC10164 being experienced.

FIGURE 1 — 1-OF-64 LINE MULTIPLEXER

The Bit chosen is dependent on six-bit code present on inputs 7, 9, 14 of the MC10161 and the A, B, C inputs of the MC10164.

MOTOROLA

MC10165

**8-INPUT
PRIORITY ENCODER**

The MC10165 is a device designed to encode eight inputs to a binary coded output. The output code is that of the highest order input. Any input of lower priority is ignored. Each output incorporates a latch allowing synchronous operation. When the clock is low the outputs follow the inputs and latch when the clock goes high. This device is very useful for a variety of applications in checking system status in control processors, peripheral controllers, and testing systems.

The input is active when high, (e.g., the three binary outputs are low when input D0 is high). The Q3 output is high when any input is high. This allows direct extension into another priority encoder when more than eight inputs are necessary. The MC10165 can also be used to develop binary codes from random logic inputs, for addressing ROMs, RAMs, or for multiplexing data.

$P_D = 545 \text{ mW typ/pkg (No Load)}$
 $t_{pd} = 4.5 \text{ ns typ (Data to Output)}$

For PLCC pin assignment, see tables on page 1-31.

MC10165

LOGIC DIAGRAM

Numbers at ends of terminals denote pin numbers for L and P packages.
 Numbers in parenthesis denote pin numbers for F package.

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established in an ambient temperature of 25°C, while the circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 lpm is maintained. Outputs are terminated through a 50-ohm resistor to 0 to -2.0 volts. Test procedures are shown for only one input, or for one set of input conditions. Other inputs tested in the same manner.

To preserve reliable performance, the MC10165P (plastic-packaged device only) is to be operated in ambient temperatures above 70°C only when 500 lfm blown air or equivalent heat sinking is provided.

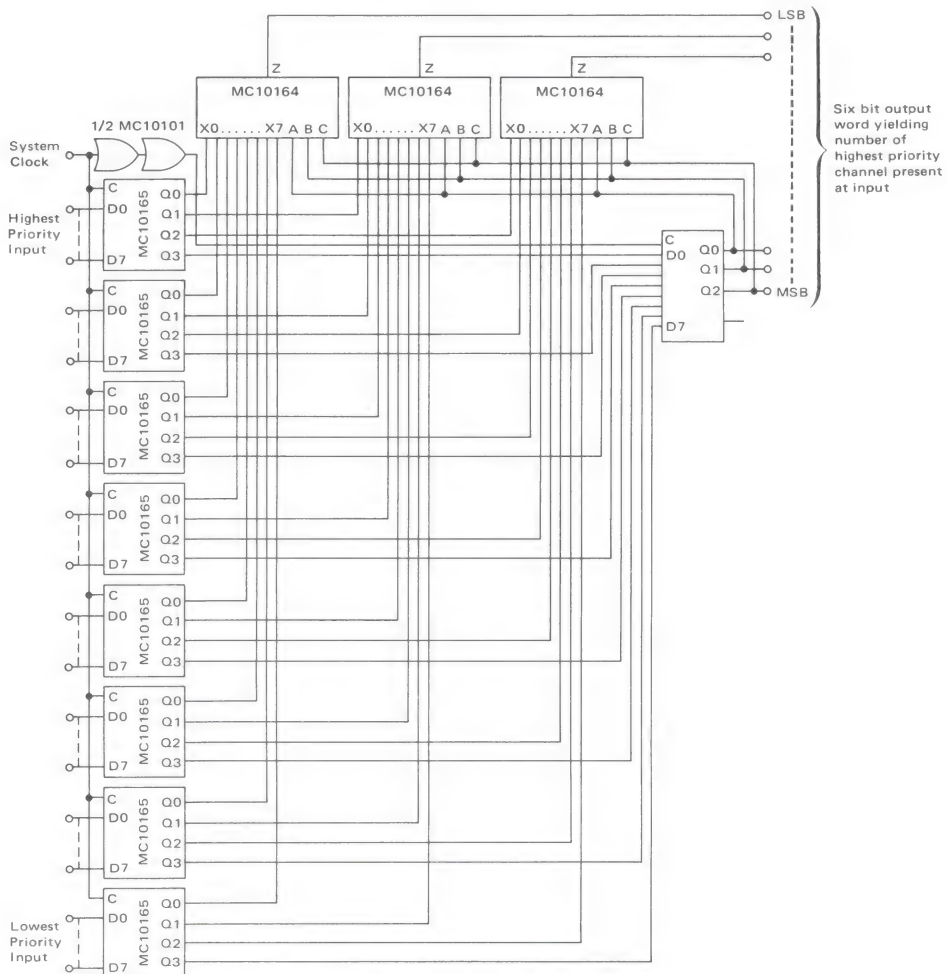

- ① The same limit applies for all D type input pins. To test input currents for other D inputs, individually apply proper voltage to pin under test.
- ② Output latched to low state prior to test.
- ③ Output latched to high state prior to test.

APPLICATION INFORMATION

A typical application of the MC10165 is the decoding of system status on a priority basis. A 64 line priority encoder is shown in the figure below. System status lines are con-

nected to this encoder such that, when a given condition exists, the respective input will be at a logic high level. This scheme will select the one of 64 different system conditions, as represented at the encoder inputs, which has priority in determining the next system operation to be performed. The binary code showing the address of the highest priority input present will appear at the encoder outputs to control other system logic functions.

64-LINE PRIORITY ENCODER

MOTOROLA

MC10166

5-BIT MAGNITUDE COMPARATOR

The MC10166 is a high speed expandable 5-bit comparator for comparing the magnitude of two binary words. Two outputs are provided: $A < B$ and $A > B$. $A = B$ can be obtained by NORing the two outputs with an additional gate. A high level on the enable function forces both outputs low. Multiple MC10166s may be used for larger word comparisons.

APPLICATION INFORMATION

FIGURE 1 — 9-BIT MAGNITUDE COMPARATOR

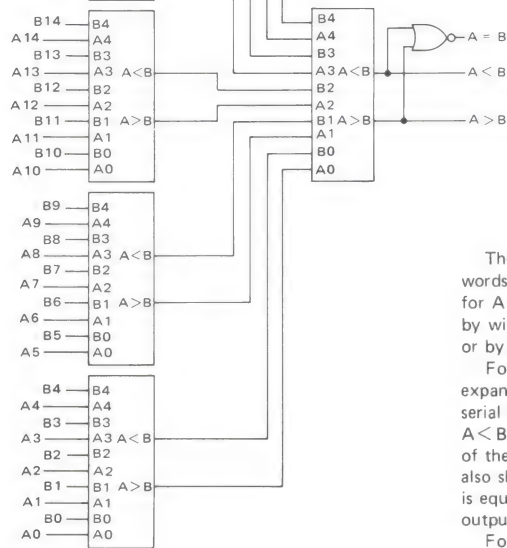

FIGURE 2 — 25-BIT MAGNITUDE COMPARATOR

The MC10166 compares the magnitude of two 5-bit words. Two outputs are provided which give a high level for $A > B$ and $A < B$. The $A = B$ function can be obtained by wire-ORing these outputs (a low level indicates $A = B$) or by NORing the outputs (a high level indicates $A = B$).

For longer word lengths, the MC10166 can be serially expanded or cascaded. Figure 1 shows two devices in a serial expansion for a 9-bit word length. The $A > B$ and $A < B$ outputs are fed to the A0 and B0 inputs respectively of the next device. The connection for an $A = B$ output is also shown. The worst case delay time of serial expansion is equal to the number of comparators times the data-to-output delay.

For shorter delay times than possible with serial expansion, devices can be cascaded. Figure 2 shows a 25-bit cascaded comparator whose worst case delay is two data-to-output delays. The cascaded scheme can be extended to longer word lengths.

MOTOROLA

MC10168

QUAD LATCH

The MC10168 is a Quad Latch with common clocking to all four latches. Separate output enabling gates are provided for each latch, allowing direct wiring to a bus. When the clock is high, outputs will follow the D inputs. Information is latched on the negative-going transition of the clock.

$P_D = 310 \text{ mW typ/pkg (No Load)}$

$t_{pd} = \bar{G} \text{ to } Q = 2 \text{ ns typ}$

$D \text{ to } Q = 3 \text{ ns typ}$

$C \text{ to } Q = 4 \text{ ns typ}$

$t_r, t_f = 2.0 \text{ ns typ (20\%-80\%)}$

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
 For PLCC pin assignment, see tables on page 1-31.

Each MECL 10,000 series has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 lpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only selected inputs and outputs. The other inputs and outputs are tested in the same manner.

* Individually test each input applying V_{IH} or V_{IL} to input under test.

MOTOROLA

MC10170

9 + 2-BIT PARITY GENERATOR-CHECKER

The MC10170 is a 11-bit parity circuit, which is segmented into 9 data bits and 2 control bits.

Output A generates odd parity on 9 bits; that is, Output A goes high for an odd number of high logic levels on the bit inputs in only 2 gate delays.

The Control Inputs can be used to expand parity to larger numbers of bits with minimal delay or can be used to generate even parity. To expand parity to larger words, the MC10170 can be used with the MC10160 or other MC10170's. The MC10170 can generate both even and odd parity.

$$P_D = 300 \text{ mW typ/pkg (No Load)}$$

$$t_{pd} = 2.5 \text{ ns typ (Control Inputs to B Output)}$$

$$4.0 \text{ ns typ (Data Inputs to A Output)}$$

$$6.0 \text{ ns typ (Data Inputs to B Output)}$$

$$t_{r,t_f} = 2.0 \text{ ns typ (20\%–80\%)}$$

MOTOROLA

MC10172

**DUAL BINARY TO 1-4-DECODER
(HIGH)**

The MC10172 is a binary-coded 2 line to dual 4 line decoder with selected outputs high. With either $\bar{E}0$ or $\bar{E}1$ low, the corresponding selected 4 outputs are low. The common enable \bar{E} , when high, forces all outputs low.

$P_D = 325 \text{ mW typ/pkg (No Load)}$
 $t_{pd} = 4.0 \text{ ns typ}$
 $t_r, t_f = 2.0 \text{ ns typ (20\%--80\%)}$

MECL 10K SERIES

**DUAL
BINARY TO 1-4-DECODER
(HIGH)**

LOGIC DIAGRAM

$V_{CC1} = \text{Pin 1}$
 $V_{CC2} = \text{Pin 16}$
 $V_{EE} = \text{Pin 8}$

PIN ASSIGNMENT**

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown only for selected inputs and outputs. Other inputs and outputs are tested in a similar manner.

MOTOROLA

MC10173

**QUAD 2-INPUT
MULTIPLEXER/LATCH**

The MC10173 is a quad two channel multiplexer with latch. It incorporates common clock and common data select inputs. The select input determines which data input is enabled. A high (H) level enables data inputs D00, D10, D20, and D30 and a low (L) level enables data inputs D01, D11, D21, D31. Any change on the data input will be reflected at the outputs while the clock is low. The outputs are latched on the positive transition of the clock. While the clock is in the high state, a change in the information present at the data inputs will not affect the output information.

$P_D = 275 \text{ mW typ/pkg (No Load)}$
 $t_{pd} = 2.5 \text{ ns typ}$
 $t_r, t_f = 2.0 \text{ ns typ (20\%--80\%)}$

**DIP
PIN ASSIGNMENT**

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts.

MOTOROLA

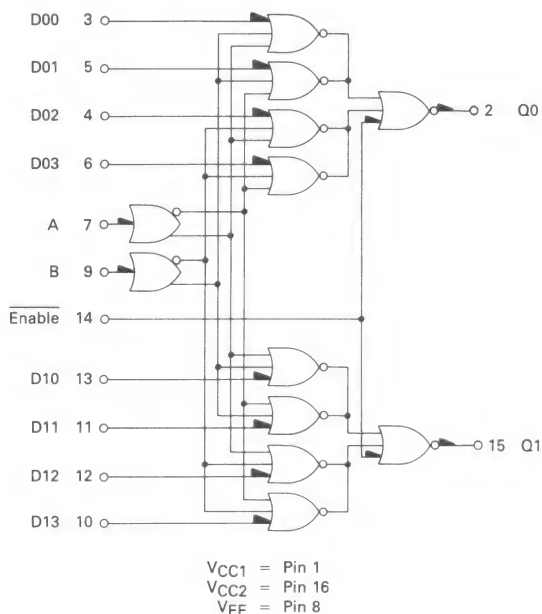

MC10174

DUAL 4 TO 1 MULTIPLEXER

The MC10174 is a high speed dual channel multiplexer with output enable capability. The select inputs determine one of four active data inputs for each multiplexer. An output enable forces both outputs low when in the high state.

$P_D = 305 \text{ mW typ/pkg (No Load)}$
 $t_{pd} = 3.5 \text{ ns typ (Data to output)}$
 $t_r, t_f = 2.0 \text{ ns typ (20\%–80\%)}$

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
 For PLCC pin assignment, see tables on page 1-31.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established in an ambient temperature of 25°C, while the circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one input, or for one set of input conditions. Other inputs tested in the same manner.

MOTOROLA

MC10175

QUINT LATCH

The MC10175 is a high speed, low power quint latch. It features five D type latches with common reset and a common two-input clock. Data is transferred on the negative edge of the clock and latched on the positive edge. The two clock inputs are "OR"ed together.

Any change on the data input will be reflected at the outputs while the clock is low. The outputs are latched on the positive transition of the clock. While the clock is in the high state, a change in the information present at the data inputs will not affect the output information. The reset input is enabled only when the clock is in the high state.

$$P_D = 400 \text{ mW typ/pkg (No Load)}$$

$$t_{pd} = 2.5 \text{ ns typ (Data to Output)}$$

$$t_r, t_f = 2.0 \text{ ns typ (20\%-80\%)}$$

DIP PIN ASSIGNMENT

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown only for selected inputs and outputs. Other inputs and outputs are tested in a similar manner.

① Individually test each input; apply V_{IH} min to pin under test.

② Output latched to high logic state prior to test.

MOTOROLA

MC10176

HEX "D" MASTER-SLAVE FLIP-FLOP

The MC10176 contains six high-speed, master slave type "D" flip-flops. Clocking is common to all six flip-flops. Data is entered into the master when the clock is low. Master to slave data transfer takes place on the positive-going Clock transition. Thus, outputs may change only on a positive-going Clock transition. A change in the information present at the data (D) input will not affect the output information any other time due to the master-slave construction of this device.

$$P_D = 460 \text{ mW typ/pkg (No Load)}$$

$$f_{\text{toggle}} = 150 \text{ MHz (typ)}$$

$$t_r, t_f = 2.0 \text{ ns typ (20\%--80\%)}$$

MOTOROLA

MC10177

**TRIPLE MECL TO
NMOS TRANSLATOR**

The MC10177 consists of three MECL to MOS translators which convert MECL 10,000 logic levels to NMOS levels. It is designed for use in N-channel memory systems as a Read/Write, Data/Address driver. It may also be used as a high fanout (30) MECL to TTL translator, or in other applications requiring the capability to drive high capacitive loads. A separate lead from each of the three translators is brought out of the package. These leads may be connected to V_{SS} or to an external capacitor (0.01 to 0.05 μF to ground), for waveform improvement, and short circuit protection. When connection is made to an external capacitor, V_{SS} line fluctuations due to transient currents are also reduced.

Max Load: 350 pF

$P_D = 1.0$ W typ/pkg @ 5.0 MHz

Operating rate: 5.0 MHz typ.

(all 3 translators in use simultaneously)

INPUT: MECL 10,000 (differential)

OUTPUT: NMOS + 0.5 V V_{OLmax}
+ 3.0 V V_{OHmin} *

$t_r, t_f = 6.0$ ns typ (20%–80%)

*May be raised by increasing V_{SS} .

SWITCHING TIME TEST CIRCUIT

SWITCHING WAVEFORMS @ 25°C

Switching times are measured after the device under test reaches a stabilized temperature (air flow ≥ 500 lfpm)

MOTOROLA

MC10178

BINARY COUNTER

The MC10178 is a four-bit counter capable of divide-by-two, divide-by-four, divide-by-eight or a divide-by-sixteen function.

Clock inputs trigger on the positive going edge of the clock pulse. Set and Reset inputs override the clock, allowing asynchronous "set" or "clear." Individual Set and common Reset inputs are provided, as well as complementary outputs for the first and fourth bits. True outputs are available at all bits.

MOTOROLA

MC10179

LOOK-AHEAD CARRY BLOCK

The MC10179 is a high speed, low power, standard MECL complex function that is designed to perform the look-ahead carry function. This device can be used with the MC10181 4-bit ALU directly, or with the MC10180 dual arithmetic unit in any computer, instrumentation or digital communication application requiring high speed arithmetic operation on long words.

When used with the MC10181, the MC10179 performs a second order or higher look-ahead. Figure 2 shows a 16-bit look-ahead carry arithmetic unit. Second order carry is valuable for longer binary words. As an example, addition of two 32-bit words is improved from 30 nanoseconds with ripple-carry techniques. A block diagram of a 32-bit ALU is shown in Figure 1. The MC10179 may also be used in many other applications. It can, for example, reduce system package count when used to generate functions of several variables.

$P_D = 300 \text{ mW typ/pkg (No Load)}$
 $t_{pd} = 3.0 \text{ ns typ (Carry, Propagate)}$
 $4.0 \text{ ns typ (Generate)}$
 $t_r, t_f = 2.3 \text{ ns typ (20\%–80\%)}$

$$C_{n-4} = (C_n + P_0 + P_1 + P_2 + P_3) (G_0 + P_1 + P_2 + P_3) (G_1 + P_2 + P_3) (G_2 + P_3) G_3$$

PIN ASSIGNMENT

Each MECL 10,000 series device has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear ft/min is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown only for selected inputs and outputs. Other inputs and outputs are tested in a similar manner.

MOTOROLA

DUAL 2-BIT ADDER/SUBTRACTOR

The MC10180 is a high speed, low power general-purpose adder/subtractor. It is designed to be used in special purpose adders/subtractors or in high speed multiplier arrays. The MC10180 can be used in any piece of equipment where these operations are necessary.

Inputs for each adder are Carry-in, operand A, and operand B; outputs are Sum, $\bar{\text{Sum}}$, and Carry-out. The common Select inputs serve as a control line to invert A for subtract, and a control line to invert B.

$$P_D = 360 \text{ mW typ/pkg (No Load)}$$

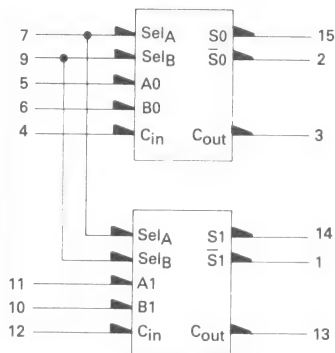

$$C_{in} \text{ to } C_{out} = 2.2 \text{ ns}$$

MOTOROLA

MC10181

4-BIT ARITHMETIC LOGIC UNIT/FUNCTION GENERATOR

The MC10181 is a high-speed arithmetic logic unit capable of performing 16 logic operations and 16 arithmetic operations on two four-bit words. Full internal carry is incorporated for ripple through operation.

Arithmetic logic operations are selected by applying the appropriate binary word to the select inputs (S0 through S3) as indicated in the tables of arithmetic/logic functions. Group carry propagate (P_G) and carry generate (G_G) are provided to allow fast operations on very long words using a second order look ahead. The internal carry is enabled by applying a low level voltage to the mode control input (M).

When used with the MC10179, full-carry look-ahead, as a second order look ahead block, the MC10181 provides high speed arithmetic operations on very long words.

$P_D = 600 \text{ mW typ/pkg (No Load)}$

$t_{pd} \text{ (typ): A1 to F} = 6.5 \text{ ns}$

$C_n \text{ to } C_{n+4} = 3.1 \text{ ns}$

A1 to $P_G = 5.0 \text{ ns}$

A1 to $G_G = 4.5 \text{ ns}$

A1 to $C_{n+4} = 5.0$

MOTOROLA

2-BIT ARITHMETIC LOGIC UNIT/FUNCTION GENERATOR

The MC10182 is a high-speed arithmetic logic unit capable of performing 4 logic operations and 4 arithmetic operations on two 2-bit words. Full internal carry is incorporated for arithmetic operation.

Arithmetic logic operations are selected by applying the appropriate binary word to the select inputs (S0 and S1) as indicated in the tables of arithmetic/logic functions. Group carry propagate (PG) and carry generate (GG) are provided for a second order look ahead carry using the MC10179. The internal carry is enabled by applying a low level voltage to the mode control input (M).

The MC10182 provides an alternate to the MC10181 four-bit ALU for applications not requiring the extended functions of the MC10181 or for applications requiring a 16-pin package. The MC10182 also differs from the MC10181 in that Word A and Word B are treated equally for addition and subtraction (A plus B, A minus B, B minus A).

$P_D = 575 \text{ mW typ/pkg (No Load)}$

$t_{pd} \text{ (typ): A1 to F} = 7.5 \text{ ns}$

$C_n \text{ to } C_{n+2} = 2.7 \text{ ns}$

A1 to $P_G = 6.5 \text{ ns}$

A1 to $G_G = 5.5 \text{ ns}$

A1 to $C_{n+2} = 7.0 \text{ ns}$

$t_r, t_f = 2.5 \text{ ns typ (20\%--80\%)}$

MOTOROLA

MC10186

**HEX "D" MASTER-SLAVE
FLIP-FLOP/WITH RESET**

The MC10186 contains six high-speed, master slave type "D" flip-flops. Clocking is common to all six flip-flops. Data is entered into the master when the clock is low. Master to slave data transfer takes place on the positive-going Clock transition. Thus, outputs may change only on a positive-going Clock transition. A change in the information present at the data (D) input will not affect the output information any other time due to the master-slave construction of this device. A common Reset is included in this circuit. Reset only functions when clock is low.

$P_D = 460 \text{ mW typ/pkg (No Load)}$
 $f_{\text{toggle}} = 150 \text{ MHz (typ)}$
 $t_r, t_f = 2.0 \text{ ns typ (20\%--80\%)}$

MOTOROLA

MC10190

QUAD MST TO MECL 10,000 TRANSLATOR

The MC10190 is a quad translator for interfacing from IBM MST-type logic signals to standard MECL 10,000 logic levels. This circuit features differential inputs for high noise environments or may be used with single ended lines by tying one of the inputs to ground. Since the MC10190 is designed to accept signals centered around ground, it is a useful interface element for many communication systems. When pin 9 is connected to V_{CC} the circuit becomes a line receiver for MECL signals. The outputs go to a low level whenever the inputs are left floating.

SWITCHING TIME TEST CIRCUIT

50-ohm termination to ground located in each scope channel input.

All input and output cables to the scope are equal lengths of 50-ohm coaxial cable. Wire length should be $< 1/4$ inch from TP_{in} to input pin and TP_{out} to output pin.

MOTOROLA

MC10192

QUAD BUS DRIVER

The MC10192 contains four line drivers with complementary outputs. Each driver has a Data (D) input and shares an Enable (\bar{E}) input with another driver. The two driver outputs are the uncommitted collectors of a pair of NPN transistors operating as a current switch. Each driver accepts 10K MECL input signals and provides a nominal signal swing of 800 mV across a 50 Ω load at each output collector. Outputs can drive higher values of load resistance, provided that the combination of I_R drop and load return voltage V_{LR} does not cause an output collector to go more negative than -2.4 V with respect to V_{CC} . To avoid output transistor breakdown, the load return voltage should not be more positive than +5.5 V with respect to V_{CC} . When the \bar{E} input is high, both output transistors of a driver are nonconducting. When not used, the \bar{E} inputs, as well as the D inputs, may be left open.

Open Collector Outputs Drive Terminated Lines or Transformers

50 k Ω Input Pulldown Resistors on All Inputs (Unused Inputs May Be Left Open)

Power Dissipation = 575 mW typ/pkg (No Load)

MOTOROLA

MC10195

HEX INVERTER/BUFFER

The MC10195 is a Hex Buffer Inverter which is built using six EXCLUSIVE NOR gates. There is a common input to these gates which when placed low or left open allows them to act as inverters. With the common input connected to a high logic level the MC10195 is a hex buffer, useful for high fanout clock driving and reducing stub lengths on long bus lines.

MOTOROLA

MC10198

MONOSTABLE MULTIVIBRATOR

The MC10198 is a retriggerable monostable multivibrator. Two enable inputs permit triggering on any combination of positive or negative edges as shown in the accompanying table. The trigger input is buffered by Schmitt triggers making it insensitive to input rise and fall times.

The pulse width is controlled by an external capacitor and resistor. The resistor sets a current which is the linear discharge rate of the capacitor. Also, the pulse width can be controlled by an external current source or voltage (see applications information).

For high-speed response with minimum delay, a hi-speed input is also provided. This input bypasses the internal Schmitt triggers and the output responds within 2 nanoseconds typically.

Output logic and threshold levels are standard MECL 10,000. Test conditions are per Table 2. Each "Precondition" referred to in Table 2 is per the sequence of Table 1.

$$P_D = 415 \text{ mW typ/pkg (No Load)}$$

SWITCHING TIME TEST CIRCUIT AND WAVEFORMS @ 25°C

APPLICATIONS INFORMATION

CIRCUIT OPERATION:

1. **PULSE WIDTH TIMING** — The pulse width is determined by the external resistor and capacitor. The MC10198 also has an internal resistor (nominally 284 ohms) that can be used in series with R_{Ext} . Pin 7, the external pulse width control, is a constant voltage node (-3.60 V nominally). A resistance connected in series from this node to V_{EE} sets a constant timing current I_T . This current determines the discharge rate of the capacitor:

$$I_T = C_{Ext} \frac{\Delta V}{\Delta T}$$

where

ΔT = pulse width

ΔV = 1.9 V change in capacitor voltage

Then:

$$\Delta T = C_{Ext} \frac{1.9 \text{ V}}{I_T}$$

If $R_{Ext} + R_{Int}$ are in series to V_{EE} :

$$I_T = [(-3.60 \text{ V}) - (-5.2 \text{ V})] \div [R_{Ext} + 284 \Omega]$$

$$I_T = 1.6 \text{ V} / (R_{Ext} + 284)$$

The timing equation becomes:

$$\Delta T = [(C_{Ext})(1.9 \text{ V})] \div [1.6 \text{ V} / (R_{Ext} + 284)]$$

$$\Delta T = C_{Ext} (R_{Ext} + 284) 1.19$$

where ΔT = Sec

R_{Ext} = Ohms

C_{Ext} = Farads

FIGURE 1 —

Figure 2 shows typical curves for pulse width versus C_{Ext} and R_{Ext} (total resistance includes R_{Int}). Any low leakage capacitor can be used and R_{Ext} can vary from 0 to 16 k-ohms.

2. **TRIGGERING** — The \bar{E}_{Pos} and \bar{E}_{Neg} inputs control the trigger input. The MC10198 can be programmed to trigger on the positive edge, negative edge, or both. Also, the trigger input can be totally disabled. The truth table is shown on the first page of the data sheet.

The device is totally retriggerable. However, as duty cycle approaches 100%, pulse width jitter can occur due to the recovery time of the circuit. Recovery time is basically dependent on capacitance C_{Ext} . Figure 3 shows typical recovery time versus capacitance at $I_T = 5 \text{ mA}$.

FIGURE 2 — TIMING PULSE WIDTH versus C_{Ext} and R_{Ext}

FIGURE 3 — RECOVERY TIME versus C_{Ext} @ $I_T = 5 \text{ mA}$

3. **HI-SPEED INPUT** — This input is used for stretching very narrow pulses with minimum delay between the output pulse and the trigger pulse. The trigger input should be disabled when using the high-speed input. The MC10198 triggers on the rising edge, using this input, and input pulse width should narrow, typically less than 10 nanoseconds.

USAGE RULES:

1. Capacitor lead lengths should be kept very short to minimize ringing due to fast recovery rise times.
2. The \bar{E} inputs should **not** be tied to ground to establish a high logic level. A resistor divider or diode can be used to establish a -0.7 to -0.9 voltage level.
3. For optimum temperature stability; 0.5 mA is the best timing current I_T . The device is designed to have a constant voltage at the EXTERNAL PULSE WIDTH CONTROL over temperature at this current value.
4. Pulse Width modulation can be attained with the EXTERNAL PULSE WIDTH CONTROL. The timing current can be altered to vary the pulse width. Two schemes are:

- (a) The internal resistor is not used. A dependent current source is used to set the timing current as shown in Figure 4. A graph of pulse width versus timing current ($C_{Ext} = 13$ pF) is shown in Figure 5.

FIGURE 5 — PULSE WIDTH versus I_T @ $C_{Ext} = 13$ pF

- (b) A control voltage can also be used to vary the pulse width using an additional resistor (Figure 6). The current ($I_T + I_C$) is set by the voltage drop across $R_{Int} + R_{Ext}$. The control current I_C modifies I_T and alters the pulse width. Current I_C should never force I_T to zero. R_C typically 1 k Ω .

 For PLCC pin assignment, see tables on page 1-31.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one gate. The other gate is tested in the same manner.

MOTOROLA

MC10216

HIGH SPEED TRIPLE LINE RECEIVER

The MC10216 is a high speed triple differential amplifier designed for use in sensing differential signals over long lines. The base bias supply (V_{BB}) is made available at pin 11 to make the device useful as a Schmitt trigger, or in other applications where a stable reference voltage is necessary.

Active current sources provide the MC10216 with excellent common mode noise rejection. If any amplifier in a package is not used, one input of that amplifier must be connected to V_{BB} (pin 11) to prevent upsetting the current source bias network.

Complementary outputs are provided to allow driving twisted pair lines, to enable cascading of several amplifiers in a chain, or simply to provide complement outputs of the input logic function.

P_D = 100 mW typ/pkg (No Load)

t_{pd} = 1.8 ns typ (Single ended)

1.5 ns typ (Differential)

t_r, t_f = 1.5 ns typ (20%–80%)

MC10231

HIGH SPEED DUAL TYPE D MASTER-SLAVE FLIP-FLOP

The MC10231 is a dual master-slave type D flip-flop. Asynchronous Set (S) and Reset (R) override Clock (C_C) and Clock Enable ($\overline{C_E}$) inputs. Each flip-flop may be clocked separately by holding the common clock in the low state and using the enable inputs for the clocking function. If the common clock is to be used to clock the flip-flop, the Clock Enable inputs must be in the low state. In this case, the enable inputs perform the function of controlling the common clock.

The output states of the flip-flop change on the positive transition of the clock. A change in the information present at the data (D) input will not affect the output information at any other time due to master-slave construction.

P_D = 270 mW typ/pkg (No Load)

t_{pd} = 2 ns typ

t_{Tog} = 225 MHz typ

t_r, t_f = 2.0 ns typ (20%–80%)

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

ELECTRICAL CHARACTERISTICS

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table after the thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one input, or for one set of input conditions. Other inputs are tested in the same manner.

MOTOROLA

MC10804 MC10805

BIDIRECTIONAL TRANSCEIVER WITH LATCH

The MC10804 and MC10805 are inverting bidirectional transceivers that interface MECL logic levels with TTL logic levels. Data can be transferred directly in either direction (MECL → TTL or TTL → MECL), and an optional gated latch is also provided. Logic levels are inverted during transfers. The MC10804 is a 4-bit version in the 16-pin package, and the MC10805 is a 5-bit version in the 20-pin package.

They make it possible to easily interface to MOS memories, TTL compatible peripherals, or existing TTL subsystems.

- Bidirectional Translation
- Power Supplies: +5.0 Volts and -5.2 Volts
- TTL Three-State Outputs
Sink 50 mA
Source 5.0 mA
- Standard MECL 50 Ohm Drive Outputs
- Latch — Can Be Bypassed for High Speed

MECL — LSI ECL/TTL INVERTING BIDIRECTIONAL TRANSCEIVERS WITH LATCH

MC10804 LOGIC DIAGRAM

MC10805 LOGIC DIAGRAM

BLOCK DIAGRAM

FUNCTIONAL DESCRIPTION

The MC10804 consists of a function decode section, a clock buffer, and four identical bit channels which perform the ECL-TTL translation. Each bit consists of a bidirectional ECL port, a bidirectional TTL port, and a latch. The MC10805 contains the same circuit blocks, but has five instead of four bits translation.

Three logic pins control the function selection. These pins, along with the clock, all operate at standard MECL levels. The block diagram and truth table define the functions. The individual pin descriptions are as follows:

Output Disable

The Output Disable, when at V_{IL} , disables both the ECL and TTL output buffers. That is, both are forced to high-impedance states. When the Output Disable is at V_{IH} the ECL/TTL translation takes place normally, and the appropriate output ports enabled by the ECL/TTL select are active. Regardless of the state of the Output Disable pin, clocked data can be loaded into the latch from the selected input port.

ECL/TTL Select

The ECL/TTL Select pin controls the direction of data

transfers. When at V_{IL} , the TTL-to-ECL direction is selected. In this case, the TTL output drivers are disabled, data is input to the latch from the TTL port, and data is output onto the ECL port. When the select pin is at V_{IH} , the ECL-to-TTL direction is selected and the function is the reverse of that just described.

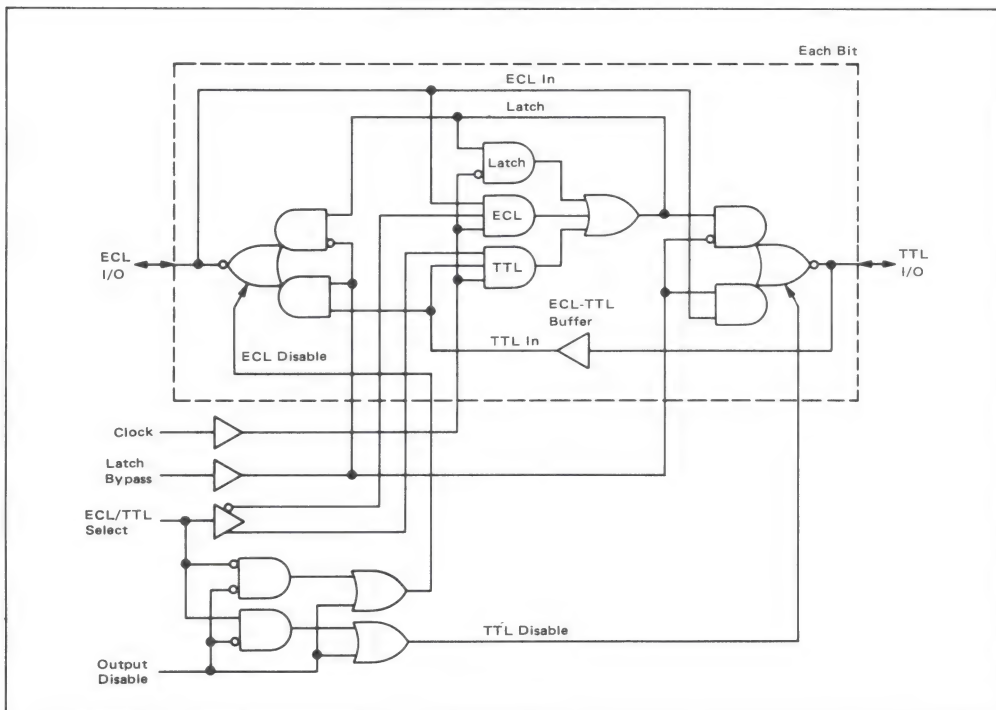

Latch Bypass

The Latch Bypass select line bypasses the latch circuitry for the fast data transfer. When the select line is at V_{IL} , the data is directed to both the latch input and the output buffer simultaneously. This feature enhances the speed of translation because the delay through the latch is bypassed. When the Latch Bypass pin is at V_{IH} , the data must first go into the latch then be sent to the output ports.

Clock

The Clock input is common to all latches and controls the storage of data. When the Clock is at V_{IL} the latch is open and data ripples through from the D input to the Q output. Data is stored or latched on the V_{IL} -to- V_{IH} transition of the Clock input.

MOTOROLA

MC1648

VOLTAGE-CONTROLLED OSCILLATOR

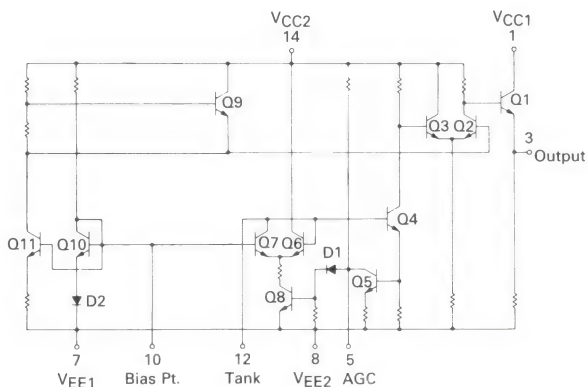

The MC1648 requires an external parallel tank circuit consisting of the inductor (L) and capacitor (C).

A varactor diode may be incorporated into the tank circuit to provide a voltage variable input for the oscillator (VCO). The MC1648 was designed for use in the Motorola Phase-Locked Loop shown in Figure 9. This device may also be used in many other applications requiring a fixed or variable frequency clock source of high spectral purity. (See Figure 2.)

The MC1648 may be operated from a +5.0 Vdc supply or a -5.2 Vdc supply, depending upon system requirements.

Supply Voltage	Gnd Pins	Supply Pins
+5.0 Vdc	7, 8	1, 14

MC1648

FIGURE 3 — TEST CIRCUIT AND WAVEFORMS

OPERATING CHARACTERISTICS

Figure 1 illustrates the circuit schematic for the MC1648. The oscillator incorporates positive feedback by coupling the base of transistor Q6 to the collector of Q7. An automatic gain control (AGC) is incorporated to limit the current through the emitter-coupled pair of transistors (Q7 and Q6) and allow optimum frequency response of the oscillator.

In order to maintain the high Q of the oscillator, and provide high spectral purity at the output, transistor Q4 is used to translate the oscillator signal to the output differential pair Q2 and Q3. Q2 and Q3, in conjunction with output transistor Q1, provides a highly buffered output which produces a square wave. Transistors Q9 and Q11 provide the bias drive for the oscillator and output buffer. Figure 2 indicates the high spectral purity of the oscillator output (pin 3).

When operating the oscillator in the voltage controlled mode (Figure 4), it should be noted that the cathode of the varactor diode (D) should be biased at least "2" VBE above VEE (≈ 1.4 V for positive supply operation).

When the MC1648 is used with a constant dc voltage

FIGURE 4 — THE MC1648 OPERATING IN THE VOLTAGE CONTROLLED MODE

to the varactor diode, the output frequency will vary slightly because of internal noise. This variation is plotted versus operating frequency in Figure 5.

NOTE: Any frequency deviation caused by the signal generator and MC1648 power supply should be determined and minimized prior to testing.

MC1648

TRANSFER CHARACTERISTICS IN THE VOLTAGE CONTROLLED MODE USING EXTERNAL VARACTOR DIODE AND COIL. $T_A = 25^\circ\text{C}$

FIGURE 6

FIGURE 7

FIGURE 8

MC1648

Typical transfer characteristics for the oscillator in the voltage controlled mode are shown in Figures 6, 7, and 8. Figures 6 and 8 show transfer characteristics employing only the capacitance of the varactor diode (plus the input capacitance of the oscillator, 6.0 pF typical). Figure 7 illustrates the oscillator operating in a voltage controlled mode with the output frequency range limited. This is achieved by adding a capacitor in parallel with the tank circuit as shown. The 1.0 k Ω resistor in Figures 6 and 7 is used to protect the varactor diode during testing. It is not necessary as long as the dc input voltage does not cause the diode to become forward biased. The larger-valued resistor (51 k Ω) in Figure 8 is required to provide isolation for the high-impedance junctions of the two varactor diodes.

The tuning range of the oscillator in the voltage controlled mode may be calculated as:

$$\frac{f_{\max}}{f_{\min}} = \frac{\sqrt{C_D(\max) + C_S}}{\sqrt{C_D(\min) + C_S}}$$

$$\text{where } f_{\min} = \frac{1}{2\pi \sqrt{L(C_D(\max) + C_S)}}$$

C_S = shunt capacitance (input plus external capacitance).

C_D = varactor capacitance as a function of bias voltage.

Good RF and low-frequency bypassing is necessary on the power supply pins. (See Figure 2.)

Capacitors (C1 and C2 of Figure 4) should be used to bypass the AGC point and the VCO input (varactor diode), guaranteeing only dc levels at these points.

For output frequency operation between 1.0 MHz and 50 MHz a 0.1 μ F capacitor is sufficient for C1 and C2. At higher frequencies, smaller values of capacitance should be used; at lower frequencies, larger values of capacitance. At high frequencies the value of bypass capacitors depends directly upon the physical layout of the system. All bypassing should be as close to the package pins as possible to minimize unwanted lead inductance.

The peak-to-peak swing of the tank circuit is set internally by the AGC circuitry. Since voltage swing of the tank circuit provides the drive for the output buffer, the AGC potential directly affects the output waveform. If it is desired to have a sine wave at the output of the MC1648, a series resistor is tied from the AGC point to the most negative power potential (ground if +5.0 volt supply is used, -5.2 volts if a negative supply is used) as shown in Figure 10.

At frequencies above 100 MHz typ, it may be desirable to increase the tank circuit peak-to-peak voltage in order to shape the signal at the output of the MC1648. This is accomplished by tying a series resistor (1.0 k Ω minimum) from the AGC to the most positive power potential (+5.0 volts if a +5.0 volt supply is used, ground if a -5.2 volt supply is used). Figure 11 illustrates this principle.

APPLICATIONS INFORMATION

The phase locked loop shown in Figure 9 illustrates the use of the MC1648 as a voltage controlled oscillator. The figure illustrates a frequency synthesizer useful in tuners for FM broadcast, general aviation, maritime and land-mobile communications, amateur and CB receivers. The system operates from a single +5.0 Vdc supply, and requires no internal translations, since all components are compatible.

Frequency generation of this type offers the advantages of single crystal operation, simple channel selection, and elimination of special circuitry to prevent harmonic lockup. Additional features include dc digital switching (preferable over RF switching with a multiple crystal system), and a broad range of tuning (up to 150 MHz, the range being set by the varactor diode).

The output frequency of the synthesizer loop is determined by the reference frequency and the number programmed at the programmable counter; $f_{\text{out}} = Nf_{\text{ref}}$. The channel spacing is equal to frequency (f_{ref}).

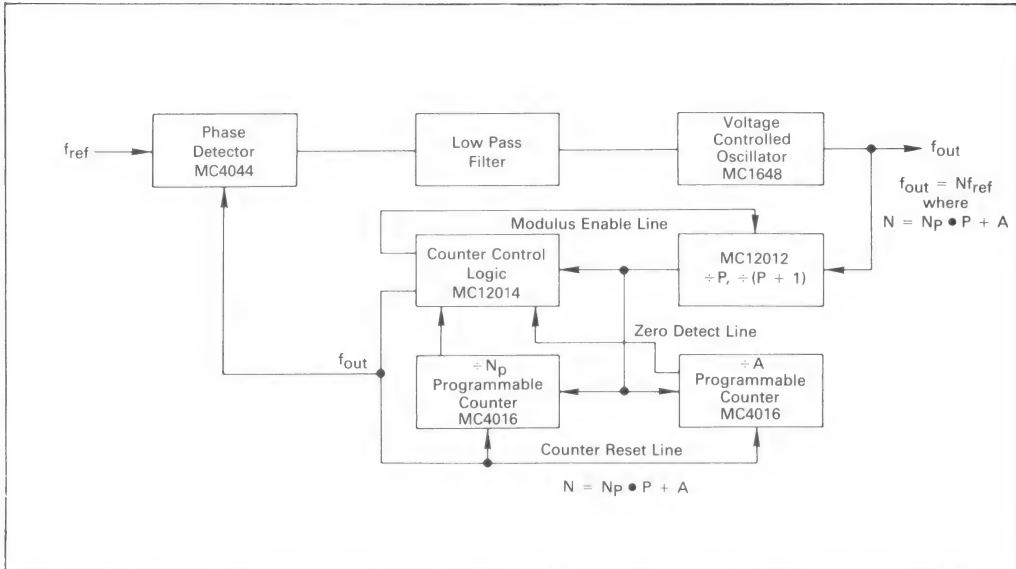

For additional information on applications and designs for phase locked-loops and digital frequency synthesizers, see Motorola Brochure BR504/D, Electronic Tuning Address Systems, (ETAS).

Figure 10 shows the MC1648 in the variable frequency mode operating from a +5.0 Vdc supply. To obtain a sine wave at the output, a resistor is added from the AGC circuit (pin 5) to V_{EE} .

Figure 11 shows the MC1648 in the variable frequency mode operating from a +5.0 Vdc supply. To extend the useful range of the device (maintain a square wave output

MC1648

FIGURE 9 — TYPICAL FREQUENCY SYNTHESIZER APPLICATION

above 175 MHz), a resistor is added to the AGC circuit at pin 5 (1.0 k-ohm minimum).

Figure 12 shows the MC1648 operating from +5.0 Vdc and +9.0 Vdc power supplies. This permits a higher voltage swing and higher output power than is possible from the MECL output (pin 3). Plots of output power versus

total collector load resistance at pin 1 are given in Figures 13 and 14 for 100 MHz and 10 MHz operation. The total collector load includes R in parallel with R_p of L1 and C1 at resonance. The optimum value for R at 100 MHz is approximately 850 ohms.

MOTOROLA

MC1650 MC1651

DUAL A/D CONVERTER

The MC1650 and the MC1651 are very high speed comparators utilizing differential amplifier inputs to sense analog signals above or below a reference level. An output latch provides a unique sample-hold feature. The MC1650 provides high impedance Darlington inputs, while the MC1651 is a lower impedance option, with higher input slew rate and higher speed capability.

The clock inputs (\bar{C}_a and \bar{C}_b) operate from MECL III or MECL 10,000 digital levels. When \bar{C}_a is at a logic high level, Q_0 will be at a logic high level provided that $V_1 > V_2$ (V_1 is more positive than V_2). \bar{Q}_0 is the logic complement of Q_0 . When the clock input goes to a low logic level, the outputs are latched in their present state.

Assessment of the performance differences between the MC1650 and the MC1651 may be based upon the relative behaviors shown in Figures 4 and 7.

BEING DISCONTINUED
(LIFETIME BUY UNTIL JUNE 14, 1989)

BINARY COUNTER

The MC1654 is a 4-bit counter capable of divide-by-two, divide-by-four, divide-by-eight, or divide-by-16 functions. When used independently, the divide-by-16 section will toggle at 325 MHz typically. Clock inputs trigger on the positive-going edge of the Clock pulse.

Set and Reset inputs override the Clock, allowing asynchronous "set" or "clear." Individual Set and common Reset inputs are provided, as well as complementary outputs for the first and fourth bits. True outputs are available at all bits.

Power Dissipation = 750 mW typ

f_{Tog} = 325 MHz typ

PIN ASSIGNMENT

MOTOROLA

MC1658

VOLTAGE-CONTROLLED MULTIVIBRATOR

The MC1658 is a voltage-controlled multivibrator which provides appropriate level shifting to produce an output compatible with MECL III and MECL 10,000 logic levels. Frequency control is accomplished through the use of voltage-variable current sources which control the slew rate of a single external capacitor.

The bias filter may be used to help eliminate ripple on the output voltage levels at high frequencies and the input filter may be used to decouple noise from the analog input signal.

PIN ASSIGNMENT

MC1670

MASTER-SLAVE FLIP-FLOP

Master slave construction renders the MC1670 relatively insensitive to the shape of the clock waveform, since only the voltage levels at the clock inputs control the transfer of information from data input (D) to output.

When both clock inputs (C1 and C2) are in the low state, the data input affects only the "Master" portion of the flip-flop. The data present in the "Master" is transferred to the "Slave" when clock inputs (C1 "OR" C2) are taken from a low to a high level. In other words, the output state of the flip-flop changes on the positive transition of the clock pulse.

While either C1 "OR" C2 is in the high state, the "Master" (and data input) is disabled.

Asynchronous Set (S) and Reset (R) override Clock (C) and Data (D) inputs.

BEING DISCONTINUED
(LIFETIME BUY UNTIL JUNE 14, 1989)

BI-QUINARY COUNTER

The MC1678 is a 4-bit counter capable of divide-by-two, divide-by-five, or divide-by-10 functions. When used independently, the divide-by-two section will toggle at 350 MHz typically, while the divide-by-five section will toggle at 325 MHz typically. Clock inputs trigger on the positive going edge of the clock pulse.

Set and Reset inputs override the clock, allowing asynchronous "set" or "clear." Individual Set and common Reset inputs are provided, as well as complementary outputs for the first and fourth bits. True outputs are available at all bits.

MC1692

APPLICATION INFORMATION

The MC1692 quad line receiver is used primarily to receive data from balanced twisted pair lines, as indicated in Figure 1. The line is driven with a MC1660 OR/NOR gate. The MC1660 is terminated with 50 ohm resistors to -2.0 volts. At the end of the twisted pair a 100 ohm termination resistor is placed across the differential line receiver inputs of the MC1692. Illustrated in Figure 2 is the sending and receiving waveforms at a data rate of 400 megabits per second over an 18 foot twisted pair

cable. The waveform picture of Figure 3 shows a 5.0 nanosecond pulse being propagated down the 18 foot line. The delay time for the line is 1.68 ns/foot.

The MC1692 may also be applied as a high frequency schmitt trigger as illustrated in Figure 4. This circuit has been used in excess of 200 MHz. The MC1692 when loaded into 50 ohms will produce an output rising edge of about 1.5 nanoseconds.

1.0 GHz DIVIDE-BY-FOUR PRESCALER

The MC1697 is a divide-by-four gigahertz prescaler in an 8 pin package. The clock input requires an ac coupled driving signal of 800 mV amplitude (typical). The clock toggles two divide-by-two stages, and the complementary outputs (50% duty cycle) are taken from the second stage.

The complementary outputs are capable of driving 50 ohm lines.

Pin 6 is available for connection of a decoupling capacitor to ground. This capacitor stabilizes the reference point which is internally coupled to the clock input.

COUNT FREQUENCY TEST CIRCUIT

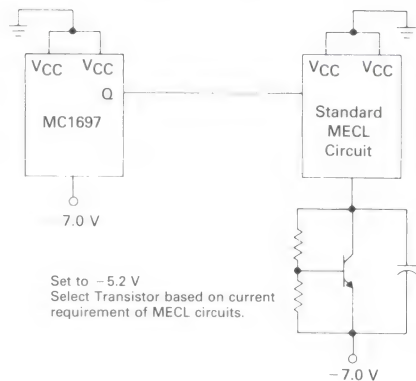

TIMING DIAGRAM

APPLICATION INFORMATION

The MC1697 is a very high speed divide-by-four prescaler designed to operate on a nominal supply voltage of -7.0 volt. In some applications it may be necessary to interface the output of the MC1697 with other MECL circuits requiring a supply voltage of -5.2 volts. One method of interfacing the circuits is shown below. This configuration is adequate for frequencies up to 1.0 GHz over the temperature range of 0° to +75°C. For best performance it is recommended that separate regulated supplies be used.

METHOD OF INTERFACING MC1697 WITH STANDARD MECL CIRCUITS

1. Enable input requires $V_{IL} = -2.0$ V max.

2. Reset counter by applying pulse P1 to pin 14, then toggle outputs by applying pulse P2 to pin 4 for 2 cycles. Hold power during pulse sequence. Hold clock input at V_{EE} .

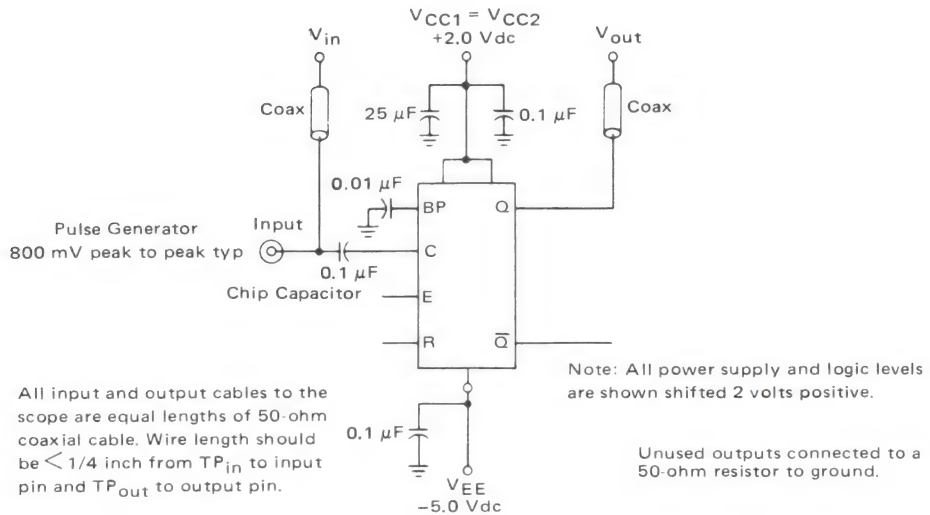

Test Conditions: $V_{CC1} = V_{CC2} = 0$, $V_{EE} = -7.0$ Vdc

MC1699

TIMING DIAGRAM

TOGGLE FREQUENCY TEST CIRCUIT

APPLICATION INFORMATION

The MC1699 is a very high speed divide-by-four counter intended for prescaler applications. The reset provides increased flexibility for counter and time measuring requirements.

The clock input is designed to accept a capacitor-coupled sine wave signal for frequencies above 100 MHz. Below 100 MHz waveshaping is recommended to obtain good MECL III or MECL 10,000 edge speeds.

With a continuous input signal the clock can be capacitor-

coupled with no problems. However, if the clock is interrupted and the clock input floats to the bias point reference voltage, the counter may oscillate. To prevent this oscillation, an external resistor can be added as shown in Figure 1. This resistor is recommended only when the clock is interrupted and serves no useful function with a continuous signal. Also, this external resistor is not required when the enable input is used to gate the clock signal.

MOTOROLA

MCM10139

256-BIT PROGRAMMABLE READ ONLY MEMORY (PROM)

The MCM10139 is a 256-bit programmable read only memory (PROM). The circuit is organized as 32 words of 8 bits. Prior to programming, all stored bits are at logic 0 (low) levels. The logic state of each bit can then be changed by on-chip programming circuitry. The MCM10139 has a single negative logic chip enable. When the chip is disabled (\overline{CS} = high), all outputs are forced to a logic 0 (low).

The MCM10139 is fully compatible with the MECL 10,000 logic family. It is designed for use in microprogramming, code conversion, logic simulation, and look-up table storage.

$P_D = 520$ mW typ/pkg (No Load)

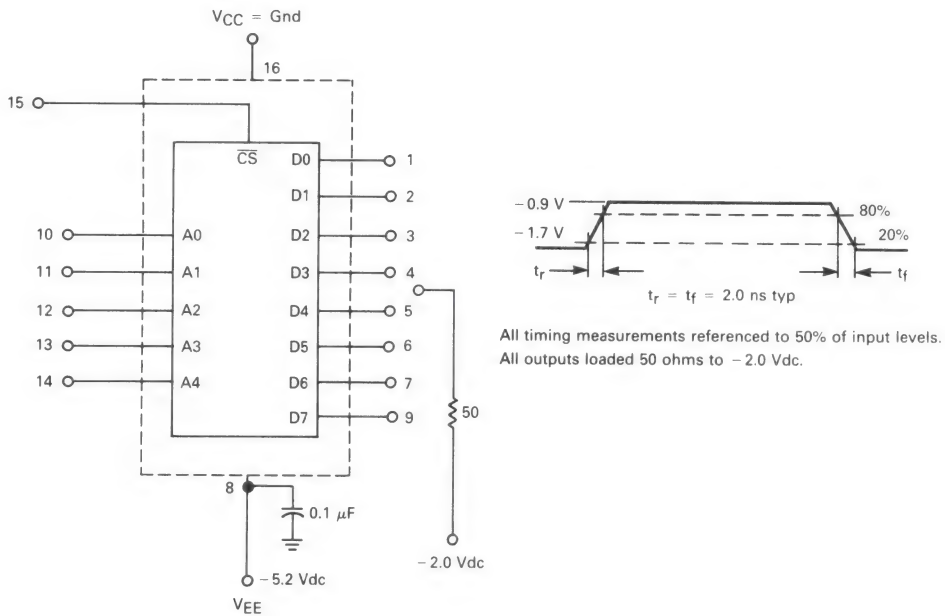

FIGURE 2 — CHIP SELECT ACCESS TIME

FIGURE 3 — ADDRESS ACCESS TIME

RECOMMENDED PROGRAMMING PROCEDURE*

The MCM10139 is shipped with all bits at logical "0" (low). To write logical "1s", proceed as follows.

MANUAL (See Figure 4)

Step 1 Connect V_{EE} (Pin 8) to -5.2 V and V_{CC} (Pin 16) to 0.0 V. Address the word to be programmed by applying -1.2 to -0.6 volts for a logic "1" and -5.2 to -4.2 volts for a logic "0" to the appropriate address inputs.

Step 2 Raise V_{CC} (Pin 16) to $+6.8$ volts.

Step 3 After V_{CC} has stabilized at $+6.8$ volts (including any ringing which may be present on the V_{CC} line), apply a current pulse of 2.5 mA to the output pin corresponding to the bit to be programmed to a logic "1".

Step 4 Return V_{CC} to 0.0 Volts.

CAUTION

To prevent excessive chip temperature rise, V_{CC} should not be allowed to remain at $+6.8$ volts for more than 1 second.

Step 5 Verify that the selected bit has programmed by connecting a $460\ \Omega$ resistor to -5.2 volts and measuring the voltage at the output pin. If a logic "1" is not detected at the output, the procedure should be repeated once. During verification V_{IH} should be -1.0 to -0.6 volts.

Step 6 If verification is positive, proceed to the next bit to be programmed.

AUTOMATIC (See Figure 5)

Step 1 Connect V_{EE} (Pin 8) to -5.2 volts and V_{CC} (Pin 16) to 0.0 volts. Apply the proper address data and raise V_{CC} (Pin 16) to $+6.8$ volts.

Step 2 After a minimum delay of $100\ \mu\text{s}$ and a maximum delay of 1.0 ms, apply a 2.5 mA current pulse to the first bit to be programmed ($0.1 \leq PW \leq 1$ ms).

Step 3 Repeat Step 2 for each bit of the selected word specified as a logic "1". (Program only one bit at a time. The delay between output programming pulses should be equal to or less than 1.0 ms.)

Step 4 After all the desired bits of the selected word have been programmed, change address data and repeat Steps 2 and 3.

NOTE: If all the maximum times listed above are maintained, the entire memory will program in less than 1 second. Therefore, it would be permissible for V_{CC} to remain at $+6.8$ volts during the entire programming time.

Step 5 After stepping through all address words, return V_{CC} to 0.0 volts and verify that each bit has programmed. If one or more bits have not programmed, repeat the entire procedure once. During verification V_{IH} should be -1.0 to -0.6 volts.

*NOTE: For devices that program incorrectly—return serialized units with individual truth tables. Noncompliance voids warranty.

MCM10143

MECL

8 x 2 MULTIPORT REGISTER FILE (RAM)

8 x 2 MULTIPORT REGISTER FILE (RAM)

The MC10143 is an 8 word by 2 bit multiport register file (RAM) capable of reading two locations and writing one location simultaneously. Two sets of eight latches are used for data storage in this LSI circuit.

WRITE

A write occurs on the positive to negative transition of the clock. Data is enabled by having the write enable (of each bit to be written) low when the clock transition is made. The written information is seen at the output on the negative to positive clock transition provided the read enable (of each bit) is at a low level. To inhibit a bit from being written, the write enable of that bit must be at a high level when the clock goes to a low state and must remain high until clock goes high. The operation of the clock and write enables can be reversed. While the clock is low, a positive to negative transition of the write enable will write into the bit addressed by A₀-A₂. The data is seen at the output on the negative to positive transition of the clock, provided the read enable is low.

READ

When the clock is high any two words may be read out simultaneously, as selected by addresses B₀-B₂ and C₀-C₂, including the word written during the preceding half clock cycle. When the clock goes low the addressed data is stored in the slaves. Level changes on the read address lines have no effect on the output until the clock again goes high. Read out is accomplished at any time by enabling output gates (B₀-B₁), (C₀-C₁).

^t_{pd}:

Clock to Data out = 5 ns (typ)

(Read Selected)

Address to Data out = 10 ns (typ)

(Clock High)

Read Enable to Data out = 2.8 ns (typ)

(Clock high, Addresses present)

P_D = 610 mW/pkg (typ no load)

MCM10144

256 x 1-BIT RANDOM ACCESS MEMORY

The MCM10144 is a 256 word x 1-bit Read/Write Random Access Memory. Data is accessed or stored by means of an 8-bit address decoded on chip. It has a non-inverting data out, a separate data in line and 3 active-low chip select lines. It has a typical access time of 17 ns and is designed for high-speed scratch pad, control, cache, and buffer storage applications.

- Typical Address Access Time = 17 ns
- Typical Chip Select Access Time = 4.0 ns
- Operating Temperature Range = 0° to +75°C
- Open Emitter Output Permits Wired-OR for Easy Memory Expansion
- 50 kΩ Input Pulldown Resistors on Chip Select
- Power Dissipation Decreases with Increasing Temperature
- Fully Compatible with MECL 10,000 Logic Family
- Pin-for-Pin Replacement for F10410

MCM10144

FUNCTIONAL DESCRIPTION:

The MCM10144 is a 256 word x 1-bit RAM. Bit selection is achieved by means of an 8-bit address A0 thru A7.

The active-low chip select allows memory expansion up to 2048 words. The fast chip select access time allows memory expansion without affecting system performance.

The operating mode of the RAM (\overline{CS} inputs low) is controlled by the \overline{WE} input. With \overline{WE} low the chip is in the write mode—the output is low and the data present at D_{in} is stored at the selected address. With \overline{WE} high the chip is in the read mode—the data state at the selected memory location is presented non-inverted at D_{out} .

MCM10145

64-BIT REGISTER FILE (RAM)

The MCM10145 is a 64-Bit RAM organized as a 16×4 array. This organization and the high speed make the MCM10145 particularly useful in register file or small scratch pad applications. Fully decoded inputs, together with a chip enable, provide expansion of memory capacity. The Write Enable input, when low, allows data to be entered; when high, disables the data inputs. The Chip Select input when low, allows full functional operation of the device; when high, all outputs go to a low logic state. The Chip Select, together with open emitter outputs allow full wire-ORing and data bussing capability. On-chip input pulldown resistors allow unused inputs to remain open.

- Typical Address Access Time = 10 ns
- Typical Chip Select Access Time = 4.5 ns
- Operating Temperature Range = 0° to $+75^{\circ}\text{C}$
- 50 k Ω Pulldown Resistors on All Inputs
- Fully Compatible with MECL 10,000
- Pin-for-Pin Compatible with the F10145

FUNCTIONAL DESCRIPTION:

This device is a 1024 x 1-bit RAM. Bit selection is achieved by means of a 10-bit address, A0 to A9.

The active-low chip select is provided for memory expansion up to 2048 words.

The operating mode of the RAM (CS input low) is controlled by the WE input. With WE low, the chip is in the write mode, the output, D_{OUT}, is low and the data state present at D_{IN} is stored at the selected address. With WE high, the chip is in the read mode and the data stored at the selected memory location will be presented non-inverted at D_{OUT}. (See Truth Table)

ELECTRICAL CHARACTERISTICS

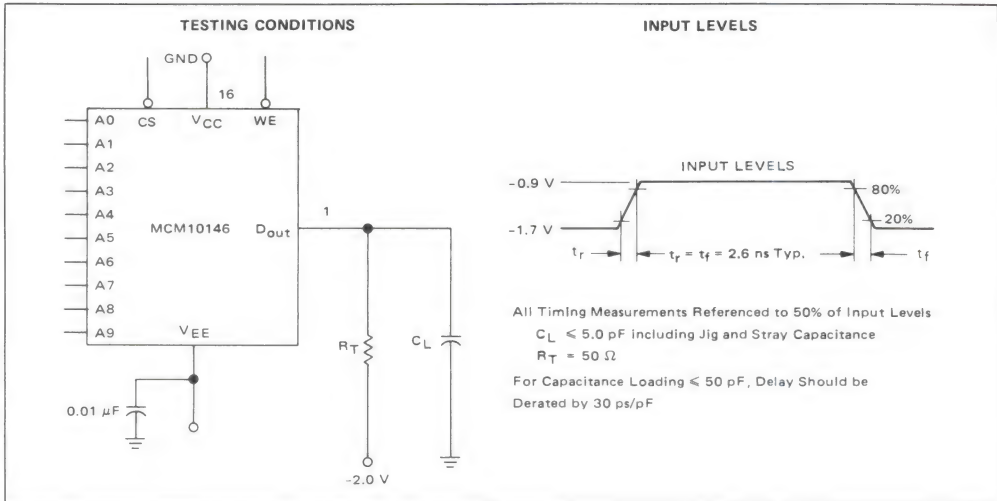

Each MECL Memory circuit has been designed to meet the dc and ac specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts.

MCM10147

128 x 1-BIT RANDOM ACCESS MEMORY

The MCM10147 is a 128-word x 1-bit Read/Write Random Access Memory. Data is accessed or stored by means of a 7-bit address decoded on chip. It has a non-inverting data out, a separate data in line and 2 active-low chip select lines. It has a typical access time of 10 ns and is designed for high-speed scratch pads, control, cache, and buffer storage applications.

- Typical Address Access Time = 10 ns
- Typical Chip Select Access Time = 5.0 ns
- Operating Temperature Range = 0° to +75°C
- Open Emitter Output Permits Wired-OR for Easy Memory Expansion
- 50 k Ω Input Pulldown Resistors on All Inputs
- Power Dissipation Decreases with Increasing Temperature
- Fully Compatible with MECL 10,000 Logic Family
- Similar to F10405.

MCM10147

FUNCTIONAL DESCRIPTION:

The MCM 10147 is a 128 word x 1-bit RAM. Bit selection is achieved by means of a 7-bit address A0 thru A6.

The active-low chip select allows memory expansion up to 512 words. The fast chip select access time allows memory expansion without affecting system performance.

The operating mode of the RAM (\overline{CS} inputs low) is controlled by the \overline{WE} input. With \overline{WE} low the chip is in the write mode—the output is low and the data present at D_{in} is stored at the selected address. With \overline{WE} high the chip is in the read mode—the data state at the selected memory location is presented non-inverted at D_{out} .

2. The maximum Address Access Time is guaranteed to be the Worst-Case Bit in the Memory.

3. For proper use of MECL Memories in a system environment, consult MECL System Design Handbook.

4. $V_{CP} = V_{CC} = \text{Gnd}$ for normal operation.

PROGRAMMING THE MCM10149*10

During programming of the MCM10149*10, input Pins 7, 9, and 10 are addressed with standard MECL 10K logic levels. However, during programming input Pins 2, 3, 4, 5, and 6 are addressed with $0 \text{ V} \leq V_{IH} \leq +0.25 \text{ V}$ and $V_{EE} \leq V_{IL} \leq -3.0 \text{ V}$. It should be stressed that this deviation from standard input levels is required only during the programming mode. During normal operation, standard MECL 10,000 input levels must be used.

With these requirements met, and with $V_{CP} = V_{CC} = 0 \text{ V}$ and $V_{EE} = -5.2 \text{ V} \pm 5\%$, the address is set up. After a minimum of 100 ns delay, V_{CP} (pin 1) is ramped up to $+10 \text{ V} \pm 0.5 \text{ V}$ (total voltage V_{CP} to V_{EE} is now

15.2 V, $+10 \text{ V} - [-5.2 \text{ V}]$). The rise time of this V_{CP} voltage pulse should be in the $1 - 10 \mu\text{s}$ range, while its pulse width (t_{W1}) should be greater than 100 μs but less than 1 ms. The V_{CP} supply current at $+10 \text{ V}$ will be approximately 525 mA while current drain from V_{CC} will be approximately 175 mA. A current limit should therefore be set on both of these supplies. The current limit on the V_{CP} supply should be set at 700 mA while the V_{CC} supply should be limited to 250 mA. It should be noted that the V_{EE} supply must be capable of sinking the combined current of the V_{CC} and V_{CP} supplies while maintaining a voltage of $-5.2 \text{ V} \pm 5\%$.

Coincident with, or at some delay after the V_{CP} pulse has reached its 100% level, the desired bit to be fused can be selected. This is done by taking the corresponding output pin to a voltage of $+2.85\text{ V} \pm 5\%$. It is to be noted that only one bit is to be fused at a time. The other three unselected outputs should remain terminated through their 50 ohm load resistor to -2.0 V . Current into the selected output is 5 mA maximum.

After the bit select pulse has been applied to the appropriate output, the fusing current is sourced out of the chip select pin 13. The 0% to 100% rise time of

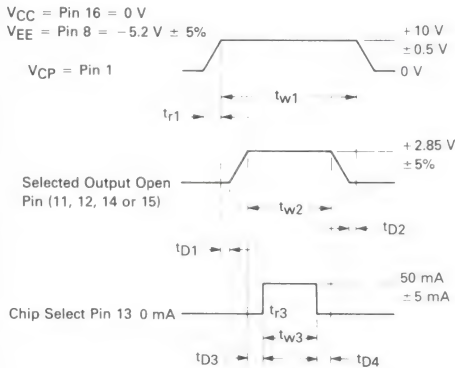

this current pulse should be 250 ns max. It pulse width should be greater than 100 μs . Pulse magnitude is 50 mA $\pm 5.0\text{ mA}$. The voltage clamp on this current source is to be -6.0 V .

After the fusing current source has returned to 0 mA, the bit select pulse is returned to its initial level, i.e., the output is returned through its load to -2.0 V . Thereafter, V_{CP} is returned to 0 V. Strobing of the outputs to determine success in programming should occur no sooner than 100 ns after V_{CP} has returned to 0 V. The remaining bits are programmed in a similar fashion.

† NOTE: For devices that program incorrectly, return serialized units with individual truth tables. Non compliance voids warranty.

PROGRAMMING SPECIFICATIONS

The following timing diagrams and fusing information represent programming specifications for the MCM10149*10.

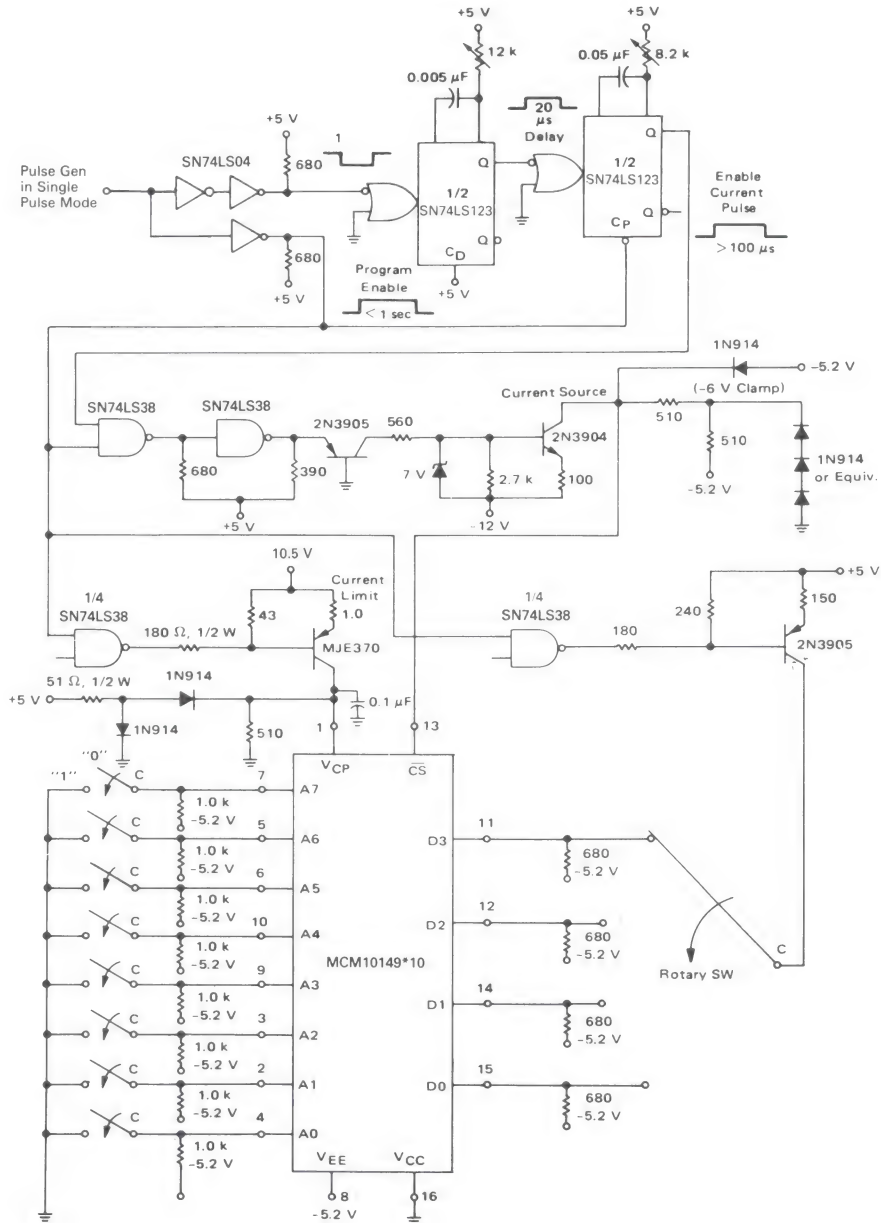

The timing diagram is shown for programming one bit. Note that only one bit is blown at a time. All addressing must be done 100 ns prior to the beginning of the V_{CP} pulse, i.e., $V_{CP} = 0\text{ V}$. Likewise, strobing of the outputs to determine success in programming should occur no sooner than 100 ns after V_{CP} returns to 0 V.

Note that the fusing current is defined as a positive current out of the chip select, pin 13. A programming duty cycle of $\leq 15\%$ is to be observed.

Definitions and values of timing symbols are as follows.

Symbol	Definition	Value
t_{r1}	Rise Time, Programming Voltage	$\geq 1\text{ }\mu\text{s}$
t_{w1}	Pulse Width, Programming Voltage	$\geq 100\text{ }\mu\text{s} < 1\text{ ms}$
t_{D1}	Delay Time, Programming Voltage Pulse to Bit Select Pulse	≥ 0
t_{w2}	Pulse Width, Bit Select	$\geq 100\text{ }\mu\text{s}$
t_{D2}	Delay Time, Bit Select Pulse to Programming Voltage Pulse	≥ 0
t_{D3}	Delay Time, Bit Select Pulse to Programming Current Pulse	$\geq 1\text{ }\mu\text{s}$
t_{r3}	Rise Time, Programming Current Pulse	250 ns max
t_{w3}	Pulse Width, Programming Current Pulse	$\geq 100\text{ }\mu\text{s}$
t_{D4}	Delay Time, Programming Current Pulse to Bit Select Pulse	$\geq 1\text{ }\mu\text{s}$

NOTES: 1. Test circuit characteristics: $R_T = 50 \Omega$, MCM10149;

$C_L \leq 5.0 \text{ pF}$ (including jig and stray capacitance)

Delay should be derated 30 ps/pF for capacitive load up to 50 pF

2. The maximum Address Access Time is guaranteed to be the Worst-Case Bit in the Memory.

3. For proper use of MECL Memories in a system environment, consult MECL System Design Handbook.

4. $V_{CP} = V_{CC} = \text{Gnd}$ for normal operation.

*To be determined; contact your Motorola representative for up-to-date information.

PROGRAMMING THE MCM10149 †

During programming of the MCM 10149, input pins 7, 9, and 10 are addressed with standard MECL 10K logic levels. However, during programming input pins 2, 3, 4, 5, and 6 are addressed with $0 \text{ V} \leq V_{IH} \leq +0.25 \text{ V}$ and $V_{EE} \leq V_{IL} \leq -3.0 \text{ V}$. It should be stressed that this deviation from standard input levels is required only during the programming mode. During normal operation, standard MECL 10,000 input levels must be used.

With these requirements met, and with $V_{CP} = V_{CC} =$

0 V and $V_{EE} = -5.2 \text{ V} \pm 5\%$, the address is set up. After a minimum of 100 ns delay, V_{CP} (pin 1) is ramped up to $+12 \text{ V} \pm 0.5 \text{ V}$ (total voltage V_{CP} to V_{EE} is now 17.2 V , $+12 \text{ V} - [-5.2 \text{ V}]$). The rise time of this V_{CP} voltage pulse should be in the $1 - 10 \mu\text{s}$ range, while its pulse width (t_{W1}) should be greater than 100 μs but less than 1 ms. The V_{CP} supply current at $+12 \text{ V}$ will be approximately 525 mA while current drain from V_{CC} will be approximately 175 mA. A current limit should therefore be

set on both of these supplies. The current limit on the V_{CP} supply should be set at 700 mA while the V_{CC} supply should be limited to 250 mA. It should be noted that the V_{EE} supply must be capable of sinking the combined current of the V_{CC} and V_{CP} supplies while maintaining a voltage of $-5.2 \text{ V} \pm 5\%$.

Coincident with, or at some delay after the V_{CP} pulse has reached its 100% level, the desired bit to be fused can be selected. This is done by taking the corresponding output pin to a voltage of $+2.85 \text{ V} \pm 5\%$. It is to be noted that only one bit is to be fused at a time. The other three unselected outputs should remain terminated through their 50 ohm load resistor to -2.0 into the selected

After the bit select pulse has been applied to the appropriate output, the fusing current is sourced out of the chip select pin 13. The 0% to 100% rise time of this current pulse should be 250 ns max. Its pulse width should be greater than 100 μs . Pulse magnitude is $50 \text{ mA} \pm 5.0 \text{ mA}$. The voltage clamp on this current source is to be -6.0 V .

After the fusing current source has returned 0 mA, the bit select pulse is returned to its initial level, i.e., the output is returned through its load to -2.0 V . Thereafter, V_{CP} is returned to 0 V. Strobing of the outputs to determine success in programming should occur no sooner than 100 ns after V_{CP} has returned to 0 V. The remaining bits are programmed in a similar fashion.

† NOTE: For devices that program incorrectly, return serialized units with individual truth tables. Non compliance voids warranty.

PROGRAMMING SPECIFICATIONS

The following timing diagrams and fusing information represent programming specifications for the MCM10149.

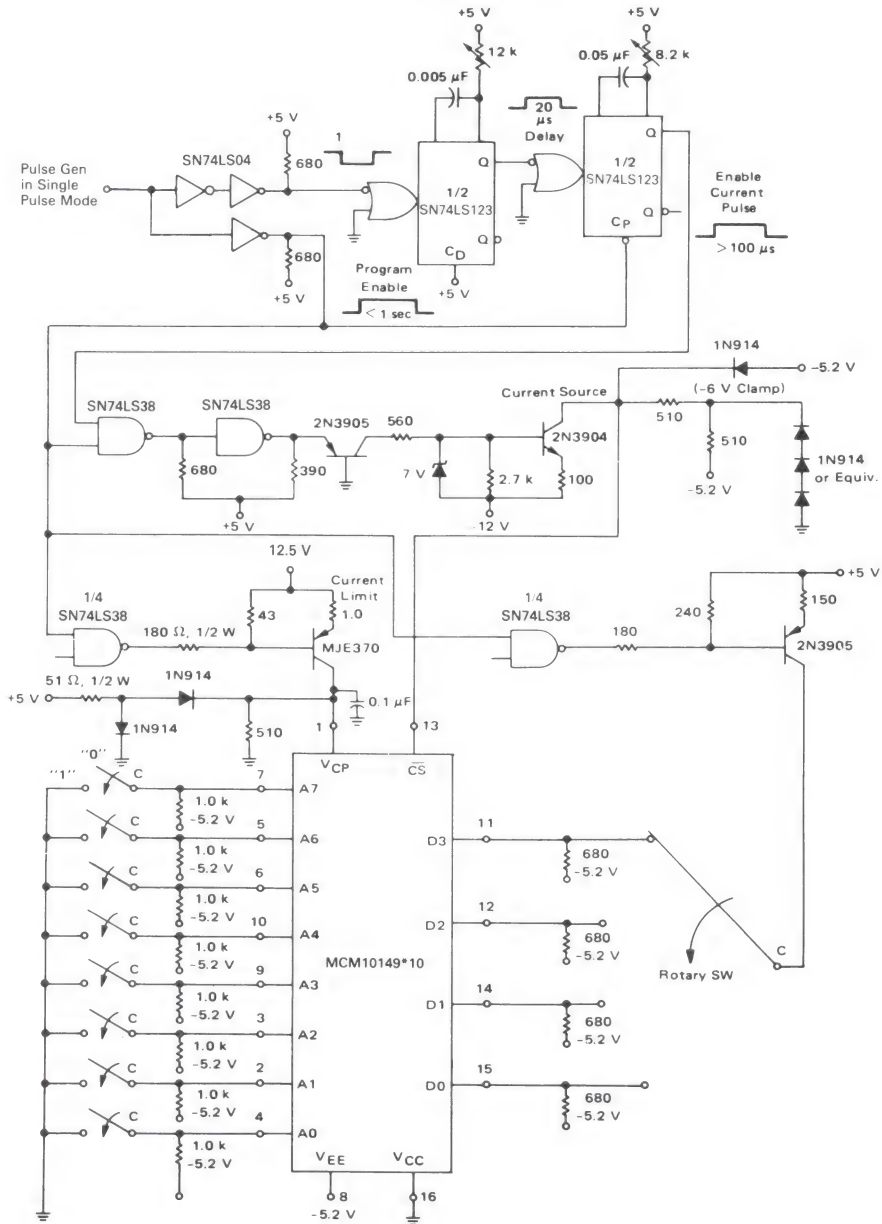

The timing diagram is shown for programming one bit. Note that only one bit is blown at a time. All addressing must be done 100 ns prior to the beginning of the V_{CP} pulse, i.e., $V_{CP} = 0 \text{ V}$. Likewise, strobing of the outputs to determine success in programming should occur no sooner than 100 ns after V_{CP} returns to 0 V.

Note that the fusing current is defined as a positive current out of the chip select, pin 13. A programming duty cycle of $\leq 15\%$ is to be observed.

Definitions and values of timing symbols are as follows.

Symbol	Definition	Value
t_{r1}	Rise Time, Programming Voltage	$\geq 1 \mu\text{s}$
t_{w1}	Pulse Width, Programming Voltage	$\geq 100 \mu\text{s} < 1 \text{ ms}$
t_{D1}	Delay Time, Programming Voltage Pulse to Bit Select Pulse	≥ 0
t_{w2}	Pulse Width, Bit Select	$\geq 100 \mu\text{s}$
t_{D2}	Delay Time, Bit Select Pulse to Programming Voltage Pulse	≥ 0
t_{D3}	Delay Time, Bit Select Pulse to Programming Current Pulse	$\geq 1 \mu\text{s}$
t_{r3}	Rise Time, Programming Current Pulse	250 ns max
t_{w3}	Pulse Width, Programming Current Pulse	$\geq 100 \mu\text{s}$
t_{D4}	Delay Time, Programming Current Pulse to Bit Select Pulse	$\geq 1 \mu\text{s}$

MCM10152

256 x 1-BIT RANDOM ACCESS MEMORY

The MCM10152 is a 256 word x 1-bit Read/Write Random Access Memory. Data is accessed or stored by means of an 8-bit address decoded on chip. It has a non-inverting data out, a separate data in line and 3 active-low chip select lines. It has a typical access time of 11 ns and is designed for high-speed scratch pad, control, cache, and buffer storage applications.

- Typical Address Access Time = 11 ns
- Typical Chip Select Access Time = 4.0 ns
- Operating Temperature Range = 0° to +75°C
- Open Emitter Output Permits Wired-OR for Easy Memory Expansion
- 50 k Ω Input Pulldown Resistors on All Inputs
- Power Dissipation Decreases with Increasing Temperature
- Fully Compatible with MECL 10,000 Logic Family

MCM10152

FUNCTIONAL DESCRIPTION:

The MCM10152 is a 256 word x 1-bit RAM. Bit selection is achieved by means of an 8-bit address A0 thru A7.

The active-low chip select allows memory expansion up to 2048 words. The fast chip select access time allows memory expansion without affecting system performance.

The operating mode of the RAM (\overline{CS} inputs low) is controlled by the \overline{WE} input. With \overline{WE} low the chip is in the write mode—the output is low and the data present at D_{in} is stored at the selected address. With \overline{WE} high the chip is in the read mode—the data state at the selected memory location is presented non-inverted at D_{out} .

PROGRAMMABLE MODULO-N COUNTERS

The monolithic devices are programmable, cascadable, modulo-N-counters. The MC4316/4016 can be programmed to divide by any number (N) from 0 thru 9, the MC4018 from 0 thru 15.

The parallel enable (PE) input enables the parallel data inputs D0 thru D3. All zeros are entered into the counter by applying a logic "0" level to the master reset (MR) and PE inputs. This causes the counter to stop counting (count = 0). All data inputs are independent of the logic level of the Clock.

Modulo-N counters are useful in frequency synthesizers, in phase-locked loops, and in other applications where a simple method for frequency division is needed.

All Types:

OPERATING CHARACTERISTICS

MC4316/4016, MC4018

Operation of both counters is essentially the same. The MC4316/4016 has a maximum modulus of ten while the MC4018 is capable of dividing by up to sixteen. Minor differences in the programming procedure will be covered in the discussion of cascaded stages.

Suitable connections for operating a single stage are shown in Figure 1, as well as appropriate waveforms. The desired modulus is applied to the data inputs D0, D1, D2, and D3 in binary (MC4018) or binary coded decimal (MC4016) positive logic format. If a number greater than nine (BCD 1001) is applied to the MC4016, it treats the most significant bit position as a zero; if for example, binary fourteen (1110) were applied to an MC4016, the counter would divide by six. BCD eight is programmed in Figure 1. As \overline{PE} is taken low the states on the parallel inputs are transferred to their respective outputs. Subsequent positive transitions of the input clock will decrement the counter until the all zero state is detected by the bus gate. The resulting positive transition of the bus line is internally inverted and fed back to the preset gating circuitry but does not yet preset the counter since the gateclock input is still high. As the clock returns to the low state the counter is set to the programmed state, taking the bus line low. The net result is one positive pulse on the bus line for every N clock pulses. The output pulse width is approximately equal to one clock pulse high time.

Operation will continue in this fashion until the data on the programmable inputs is changed. Since the preset circuitry is inhibited except when the counter is in the

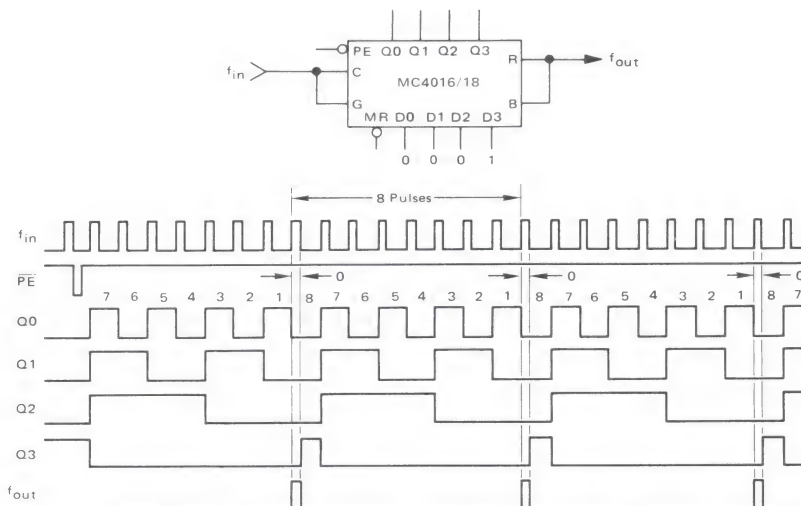

zero state, preset data may be changed while clocking is occurring. If it is necessary to enter a new number before the counter has reached zero this can be done by momentarily taking \overline{PE} low. Countdown will continue from the new number on the next positive clock transition.

The counters can be made to divide by 10 (MC4016) or 16 (MC4018) by inhibiting the preset logic. This may be done by either holding the gate input high or by holding the bus line low.

The normal connections for cascading stages are indicated in Figure 2, with the appropriate waveforms. Note that the gate input of each stage is connected to the clock; all bus outputs are tied to one of the internal pullup resistors, R. The total modulus for cascaded MC4016s is determined from $N_T = N_0 + 10N_1 + 100N_2 + \dots$; N_T for MC4018s is given by $N_T = N_0 + 16N_1 + 256N_2 + \dots$. Stated another way, the BCD equivalent of each decimal digit is applied to respective MC4016 stages while the data inputs of the MC4018 stages are treated as part of one long binary number. The difference in programming is illustrated in Figure 2 where $N_T = 245$ is coded for both counter types.

Cascaded operation can be further clarified by referring to the timing diagram of Figure 2. For the MC4016, counting begins with the first positive clock transition after the data has been set in. After the five clock pulses, the least-significant stage has been counted down to zero. The bus line does not go high at this time since the three bus terminals are wire-ORed and the other two stages are not in the zero state. Since no reset occurs, the next positive

FIGURE 1 — SINGLE-STAGE OPERATION

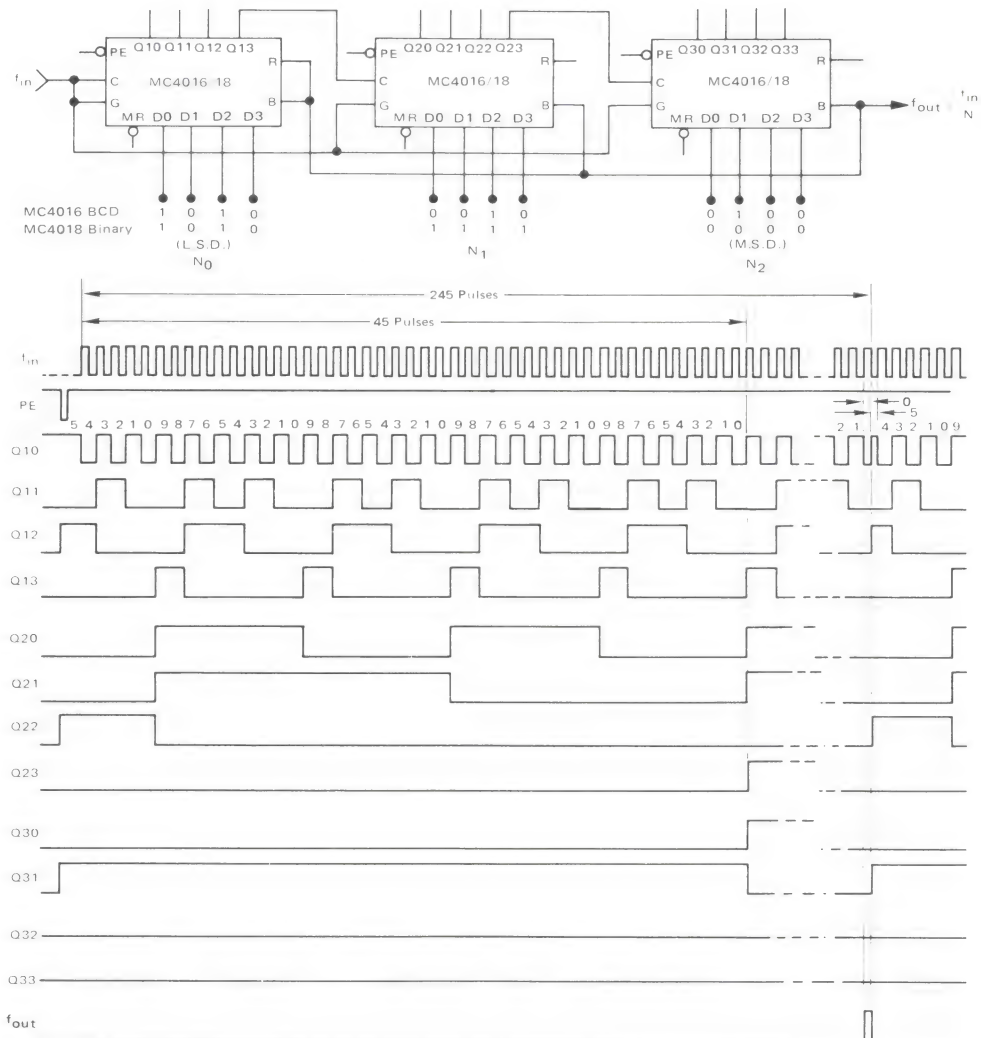

OPERATING CHARACTERISTICS: MC4316/4016, MC4018

clock edge advances the least significant stage to the nine (1001) state, causing the second stage to be decremented. The process continues in this manner with the least significant stage now dividing by ten. The second stage eventually counts down to zero and also reverts to di-

viding by ten. Each pulse out of the second stage decrements the third until it reaches zero. At this time the bus line goes high; it remains high until the clock goes low, causing all three stages to be reset to the programmed count again.

FIGURE 2 — CASCADED OPERATION

APPLICATIONS INFORMATION

A typical system application for programmable counters is illustrated in the frequency synthesizer shown in Figure 4. There the counter provides a means of digitally selecting some integral multiple of a stable reference frequency. The circuit phase locks the output, f_{VCO} , of a voltage controlled oscillator to a reference frequency, f_{ref} .¹ Circuit operation is such that $f_{VCO} = Nf_{ref}$, where N is the divider ratio of the feedback counter.

In many synthesizer applications the VCO is operated at VHF frequencies too high for direct division by TTL counters. In these cases the VCO output is usually prescaled by using a suitable fixed divide-by-M ECL circuit as shown in Figure 5. For this configuration, $f_{VCO} = NMf_{ref}$, where N is variable (programmable) and M is fixed. Design of the optimum loop filter requires that the input reference frequency be as high as possible where

FIGURE 4 — MTTL PHASE-LOCKED LOOP

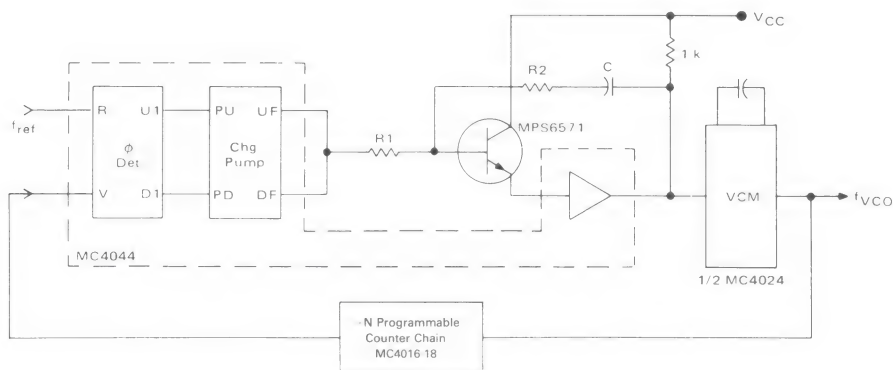

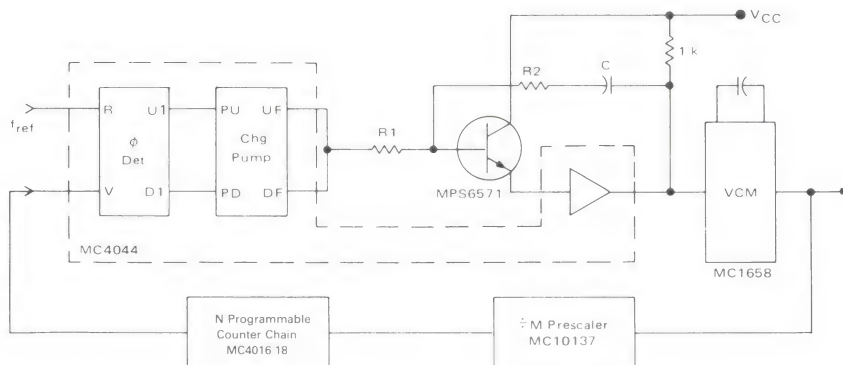

FIGURE 5 — MTTL-MECL PHASE-LOCKED LOOP

¹ See Motorola Application Note AN 535 and the MC4344/4044 Data Sheet for detailed explanation of overall circuit operation.

FIGURE 6 — FEEDBACK COUNTERS WITH DUAL MODULUS PRESCALER

the upper limit is established by the required channel spacing. Since $f_{VCO} = N f_{ref}$ in the non-prescaled case, if N is changed by one, the VCO output changes by f_{ref} , or the synthesizer channel spacing is just equal to f_{ref} . When the prescaler is used as in Figure 5, $f_{VCO} = N M f_{ref}$, and a change of one in N results in the VCO changing by $M f_{ref}$, i.e., if f_{ref} is set equal to the minimum permissible channel spacing as is desirable, then only every M channels in a given band can be selected. One solution is to set $f_{ref} = \text{channel spacing}/M$ but this leads to more stringent loop filter requirements.

An alternate approach that avoids this problem is provided by the counter configuration shown in Figure 6.² It too uses a prescaler ahead of a programmable counter, however the modulus of the prescaler is now controlled by a third counter, causing it to alternate between M and $M + 1$. Operation is best explained by assuming that all three counters have been set for the beginning of a cycle: the prescaler for division by $(M + 1)$, the modulus control

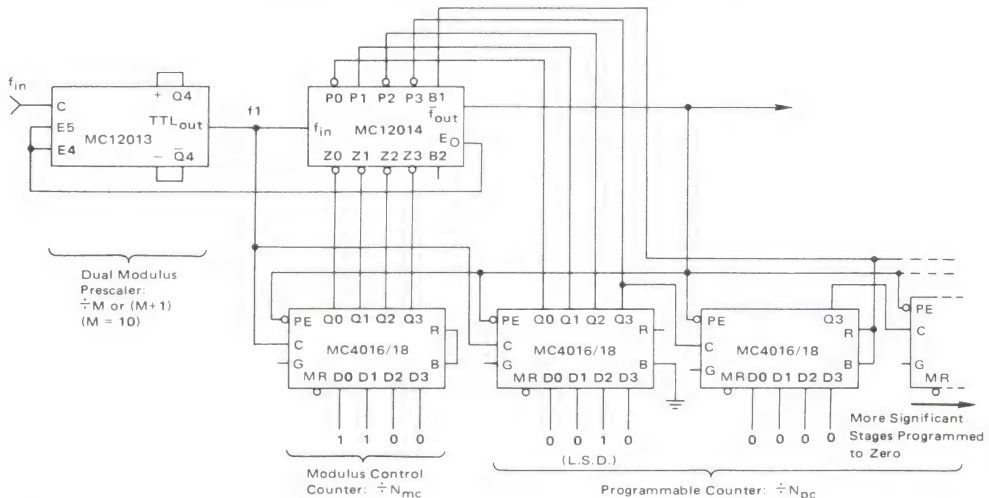

counter for division by N_{mc} , and the programmable counter for division by N_{pc} . The prescaler will divide by $(M + 1)$ until the modulus control counter has counted down to zero; at this time, the all zero state is detected and causes the prescaler to divide by M until the programmable counter has also counted down to zero. When this occurs, a cycle is complete and each counter is reset to its original modulus in readiness for the next cycle. For this configuration,

$$f_{out} = \frac{f_{in}}{M N_{pc} + N_{mc}}$$

In terms of the synthesizer application, $f_{VCO} = (M N_{pc} + N_{mc}) f_{ref}$ and channels can be selected every f_{ref} by letting N_{pc} and N_{mc} take on suitable integer values, including zero.

A simplified example of this technique is shown in Figure 7. The MC12013 Dual Modulus Prescaler divides by either 10 or 11 when connected as shown in Figure 7. If the E3 and E4 Enable inputs are high at the start of a prescaler cycle, division by 10 results; if the Enable inputs are low at the beginning of the cycle, division by 11 results. The zero detection circuitry of the MC12014 Counter Control Logic is connected to monitor the outputs of the modulus control counter; this provides a suitable enable signal at E0 as the modulus control counter reaches its terminal (zero) count. The remainder of the MC12014 is connected to extend the operating frequency of the programmable counter chain.

A specific example of this technique is shown in Figure 8. There the feedback divider circuitry required for generating frequencies between 144 MHz and 178 MHz with 30 kHz channel spacing is shown.²

FIGURE 7 — FREQUENCY DIVISION: $f_O = f_{in}/M N_{pc} + N_{mc}$ 

2. This application is discussed in greater detail in the MC12014 Counter Control Logic data sheet.

FIGURE 8 – 144 TO 178 MHz FREQUENCY SYNTHESIZER
WITH 30 kHz CHANNEL SPACING

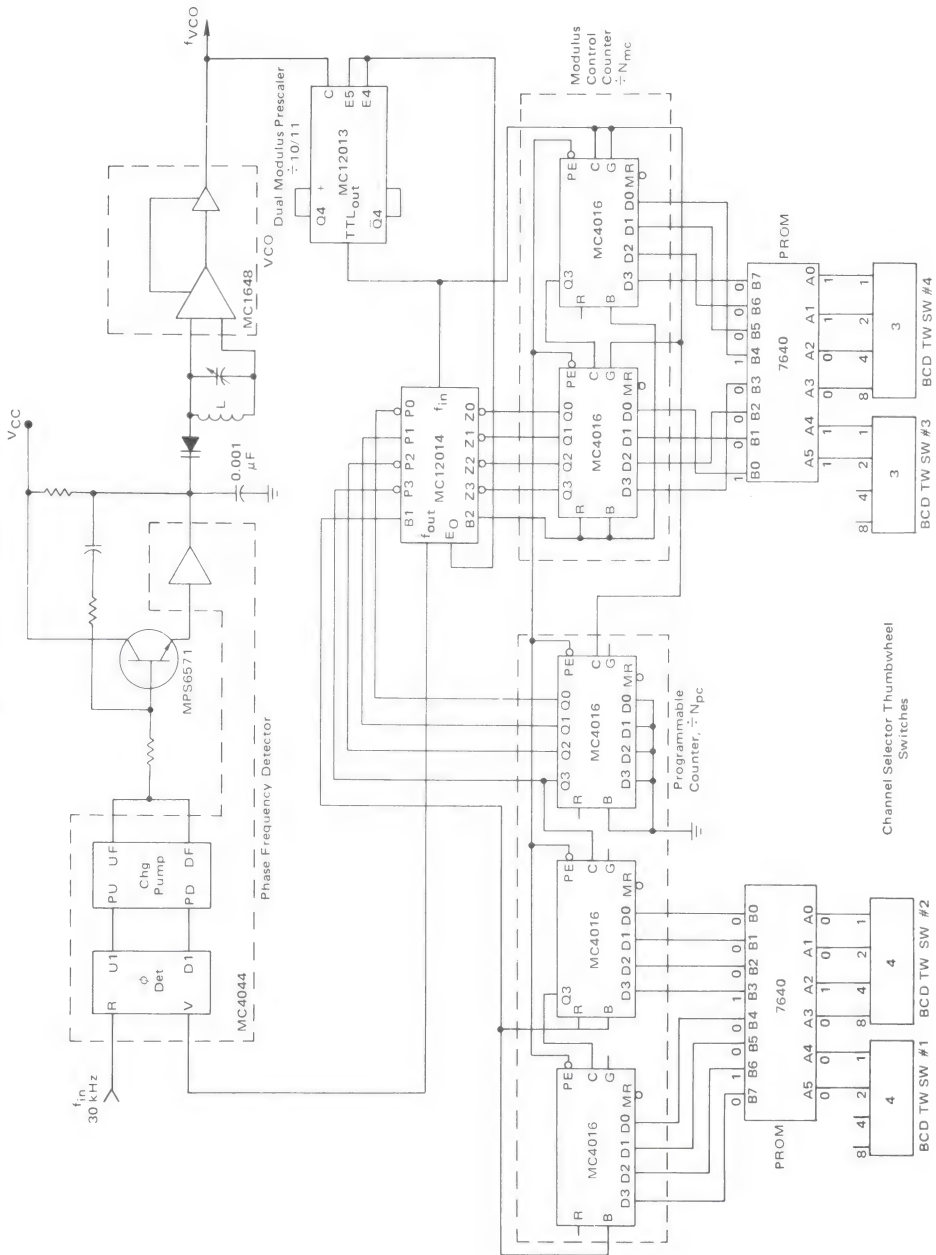

Figure 9 shows a frequency synthesizer system for the aircraft band of 108 to 136 MHz with a channel spacing of 50 kHz. For a system of this type it is desirable to use direct-reading thumbwheel switches for channel selection. To implement this system with these constraints, it is necessary to calculate the required reference frequency (f_{ref}). Figure 9 requires a reference frequency of 10 kHz and N_4 must be programmed to only 0 and 5.

For any phase-locked loop system it is desirable to maintain as high a reference frequency as possible while meeting the system requirements. The higher the reference frequency, the higher the number of sampling pulses received by the phase detector per unit time. This results in (1) easier filtering of the control voltage,

(2) faster lock-up time, and (3) less noise in the output spectrum. The higher reference frequency is also desirable because the reference frequency appears as sidebands on the output frequency and the farther the sidebands are away from the output the better the system. Another advantage of the higher reference frequency is the smaller divide ratio required in the programmable counter chain. This is advantageous when calculating realizable resistors for the filter.

Figure 10 shows the implementation of the aircraft band synthesizer with 25 kHz channel spacing (the 25 kHz spacing has been proposed to the FCC). Figure 10 shows the system using an MC4018 as the first counter, and has a reference frequency of 6.25 kHz to obtain the direct programming.

MOTOROLA

**MC4324
MC4024**

DUAL VOLTAGE-CONTROLLED MULTIVIBRATOR

The MC4324/4024 consists of two independent voltage-controlled multivibrators with output buffers. Variation of the output frequency over a 3.5-to-1 range is guaranteed with an input dc control voltage of 1.0 to 5.0 voltage.

Operating frequency is specified at 25 MHz at 25°C. Operation to 15 MHz is possible over the specified temperature range. For higher frequency requirements, see the MC1648 (200 MHz) or the MC1658 (125 MHz) data sheet.

This device was designed specifically for use in phase-locked loops for digital frequency control. It can also be used in other applications requiring a voltage-controlled frequency, or as a stable fixed frequency oscillator (3.0 MHz to 15 MHz) by replacing the external control capacitor with a series mode crystal.

APPLICATIONS INFORMATION

Suggested Design Practices

Three power supply and three ground connections are provided in this circuit (each multivibrator has separate power supply and ground connections, and the output buffers have common power supply and ground pins). This provides isolation between VCM's and minimizes the effect of output buffer transients on the multivibrators in critical applications. The separation of power supply and ground lines also provides the capability of disabling one VCM by disconnecting its V_{CC} pin. However, all ground lines must always be connected to insure substrate grounding and proper isolation.

General design rules are:

1. Ground pins 5, 7, and 9 for all applications, including those where only one VCM is used.
2. Use capacitors with less than 50 nA leakage at plus and minus 3.0 volts. Capacitance values of 15 pF or greater are acceptable.
3. When operated in the free running mode, the minimum voltage applied to the DC Control input should be 60% of V_{CC} for good stability. The maximum voltage at this input should be $V_{CC} + 0.5$ volt.
4. When used in a phase-locked loop, the filter design should have a minimum DC Control input voltage of 1.0 volt and a maximum voltage of $V_{CC} + 0.5$ volt. The maximum restriction may be waived if the output impedance of the driving device is such that it will not source more than 10 mA at a voltage of $V_{CC} + 0.5$ volt.
5. The power supply for this device should be bypassed with a good quality RF-type capacitor of 500 to 1000 pF. Bypass capacitor lead lengths should be kept as short as possible. For best results, power

supply voltage should be maintained as close to +5.0 V as possible. Under no conditions should the design require operation with a power supply voltage outside the range of 5.0 volts \pm 10%.

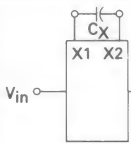

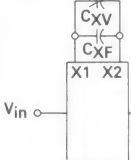

External Control Capacitor (C_X) Determination (See Table 1)

The operating frequency range of this multivibrator is controlled by the value of an external capacitor that is connected between X1 and X2. A tuning ratio of 3.5-to-1 and a maximum frequency of 25 MHz are guaranteed under ideal conditions ($V_{CC} = 5.0$ volts, $T_A = 25^\circ\text{C}$). Under actual operating conditions, variations in supply voltage, ambient temperature, and internal component tolerances limit the tuning ratio (see Figures 7 thru 12). An improvement in tuning ratio can be achieved by providing a variable tuning capacitor to facilitate initial alignment of the circuit.

Figures 5 through 9 show typical and suggested design limit information for important VCM characteristics. The suggested design limits are based on operation over the specified temperature range with a supply voltage of 5.0 volts \pm 5% unless otherwise noted. They include a safety factor of three times the estimated standard deviation.

Figures 5 and 6 provide data for any external control capacitor value greater than 100 pF. With smaller capacitor values, the curves are effectively moved downward. For example, a typical curve of frequency versus control voltage would be very nearly identical to the lower suggested design limit of Figure 5 if a 15 pF capacitor is used. To use Figure 5 divide on the ordinate by the capacitor

value in picofarads to obtain output frequency in megahertz. In Figure 6 the ordinate axis is multiplied by the capacitor value in picofarads to obtain the gain constant (K_Y) in radians/second/volt.

Frequency Stability

When the MC4324/4024 is used as a fixed-frequency oscillator (V_{in} constant), the output frequency will vary slightly because of internal noise. This variation is indicated by Figure 10 for the circuit of Figure 11. These variations are relatively independent ($< 10\%$) of changes in temperature and supply voltage.

10-to-1 Frequency Synthesizer

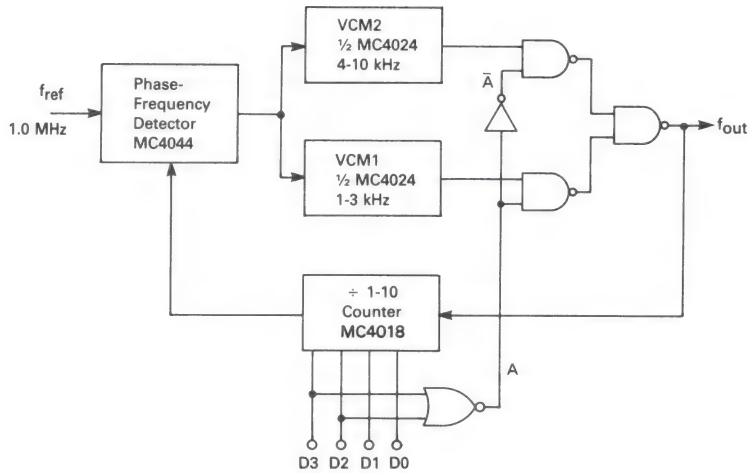

A frequency synthesizer covering a 10-to-1 range is shown in Figure 14. Three packages are required to complete the loop: The MC4344/4044 phase-frequency detector, the MC4324/4024 dual voltage-controlled multi-vibrator, and the MC4318/4018 programmable counter.

Two VCM's (one package) are used to obtain the required frequency range. Each VCM is capable of operating over a 3-to-1 range, thus VCM1 is used for the lower portion of the times ten range and VCM2 covers the upper end. The proper divide ratio is set into the programmable counter and the VCM for that frequency is selected by control gates. The other VCM is left to be free running since its output is gated out of the feedback path.

Normally with a single VCM the loop gain would vary over a 10-to-1 range due to the range of the counter ratios. This affects the bandwidth, lockup time, and damping ratio severely. Utilizing two VCM's reduces this change in loop gain from 10-to-1 to 3-to-1 as a result of the different sensitivities of the two VCM's due to the different frequency ranges. This change of VCM sensitivity (3-to-1) is of such a direction of compensate for loop gain variations due to the programmable counter.

The overall concept of multi-VCM operation can be expanded for ranges greater than 10-to-1. Four VCM's (two packages) could be used to cover a 100-to-1 range.

MC4044**

PHASE-FREQUENCY DETECTOR

The MC4344/4044 consists of two digital phase detectors, a charge pump, and an amplifier. In combination with a voltage controlled multivibrator (such as the MC4324/4024 or MC1648), it is useful in a broad range of phase-locked loop applications. The circuit accepts TTL waveforms at the R and V inputs and generates an error voltage that is proportional to the frequency and/or phase difference of the input signals. Phase detector #1 is intended for use in systems requiring zero frequency and phase difference at lock. Phase detector #2 is used if quadrature lock is desired. Phase detector #2 can also be used to indicate that the main loop, utilizing phase detector #1, is out of lock.

TRUTH TABLE

This is not strictly a functional truth table; i.e., it does not show all possible modes of operation. It is useful for dc testing.

1. X indicates output state unknown.
2. U1 and D1 outputs are sequential; i.e., they must be sequenced in order shown.
3. U2 and D2 outputs are combinational; i.e., they need only inputs shown to obtain outputs.

Note 1. The output state of Pin 2 and Pin 13 depends upon the sequence that has been applied to the R and V inputs as shown in the Truth Table. In testing output voltage, the outputs of the device are tested by sequencing through the indicated input states according to the Truth Table. Procedures identified by a double asterisk (**) are necessary to change the state of the sequential logic. When testing I_{OS} and I_{OLK} on Pin 2 or 13, a single asterisk (*) indicates that the R and V inputs are sequenced per the Truth Table to input state 11 where the tests are performed. All input, power supply, and ground voltages must be maintained while sequencing and testing unless otherwise noted.

APPLICATION

Operation of the MC4344/4044 is best explained by initially considering each section separately. If phase detector #1 is used, loop lockup occurs when both outputs U1 and D1 remain high. This occurs only when all the negative transitions on R, the reference input, and V, the variable or feedback input, coincide. The circuit responds only to transitions, hence phase error is independent of input waveform duty cycle or amplitude variation. Phase detector #1 consists of sequential logic circuitry, therefore operation prior to lockup is determined by initial conditions.

When operation is initiated, by either applying power to the circuit or active input signals to R and V, the circuitry can be in one of several states. Given any particular starting conditions, the flow table of Figure 1 can be used to determine subsequent operation. The flow table indicates the status of U1 and D1 as the R and V inputs are varied. The numbers in the table which are in parentheses are arbitrarily assigned labels that correspond to stable states that can result for each input combination. The numbers without parentheses refer to unstable conditions. Input changes are traced by horizontal movement in the table; after each input change, circuit operation will settle in the numbered state indicated by moving horizontally to the appropriate R-V column. If the number at that location is not in parentheses, move vertically to the number of the same value that is in parentheses. For a given input pair, any one of three stable states can exist. As an example, if $R = 1$ and $V = 0$, the circuit will be in one of the stable states (4), (8), or (12).

FIGURE 1 — PHASE DETECTOR #1 FLOW TABLE

R-V	R-V	R-V	R-V	U1	D1
0-0	0-1	1-1	1-0		
(1) 5 (5) 9 5 5 (9) 5	2 (2) 6 (6) 2 (10) 6	3 (3) 7 (7) 2 (11)	(4) 8 8 12 (8) 12 (12)	0 0 1 1 1 1 1 0 1	1 1 1 1 1 0 0

Use of the table in determining circuit operation is illustrated in Figure 2. In the timing diagram, the input to R is the reference frequency; the input to V is the same frequency but lags in phase. Stable state (4) is arbitrarily assumed as the initial condition. From the timing diagram and flow table, when the circuit is in stable state (4), outputs U1 and D1 are "0" and "1" respectively. The next input state is $R-V = 1-1$; moving horizontally from stable state (4) under $R-V = 1-0$ to the $R-V = 1-1$ column, state 3 is indicated. However, this is an unstable condition and the circuit will assume the state indicated by moving vertically in the $R-V = 1-1$ column to stable state (3). In this

FIGURE 2 — PHASE DETECTOR #1 TIMING DIAGRAM

instance, outputs U1 and D1 remain unchanged. The input states next become $R-V = 0-1$; moving horizontally to the $R-V = 0-1$ column, stable state (2) is indicated. At this point there is still no change in U1 or D1. The next input change shifts operation to the $R-V = 0-0$ column where unstable state 5 is indicated. Moving vertically to stable state (5), the outputs now change state to $U1-D1 = 1-1$. The next input change, $R-V = 1-0$, drives the circuitry to stable state (8), with no change in U1 or D1. The next input, $R-V = 1-1$, leads to stable state (7) with no change in the outputs. The next two input state changes cause U1 to go low between the negative transitions of R and V. As the inputs continue to change, the circuitry moves repeatedly through stable states (2), (5), (8), (7), (2), etc., as shown, and a periodic waveform is obtained on the U1 terminal while D1 remains high.

A similar result is obtained if V is leading with respect to R, except that the periodic waveform now appears on D1 as shown in rows e-h of the timing diagram of Figure 2. In each case, the average value of the resulting waveform is proportional to the phase difference between the two inputs. In a closed loop application, the error signal for controlling the VCO is derived by translating and filtering these waveforms.

The results obtained when R and V are separated by a fixed frequency difference are indicated in rows i-l of the timing system. For this case, the U1 output goes low when R goes low and stays in that state until a negative transition on V occurs. The resulting waveform is similar

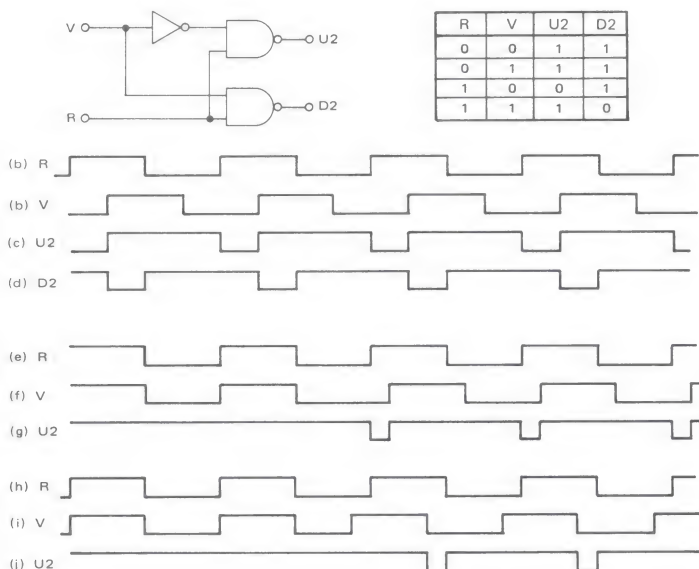

to the fixed phase difference case, but now the duty cycle of the U1 waveform varies at a rate proportional to the difference frequency of the two inputs, R and V. It is this characteristic that permits the MC4344/4044 to be used as a frequency discriminator; if the signal on R has been frequency modulated and if the loop bandwidth is selected to pass the deviation frequency but reject R and V, the resulting error voltage applied to the VCO will be the recovered modulation signal.

Phase detector #2 consists only of combinatorial logic, therefore its characteristics can be determined from the simple truth table of Figure 3. Since circuit operation requires that both inputs to the charge pump either be high or have the same duty cycle when lock occurs, using this phase detector leads to a quadrature relationship between R and V. This is illustrated in rows a-d of the timing diagram of Figure 3. Note that any deviation from a fifty percent duty cycle on the inputs would appear as phase error.

Waveforms showing the operation of phase detector #2 when phase detector #1 is being used in a closed loop are indicated in rows e-j. When the main loop is locked, U2 remains high. If the loop drifts out of lock in either direction a negative pulse whose width is proportional to the amount of drift appears on U2. This can be used to generate a simple loss-of-lock indicator.

Operation of the charge pump is best explained by considering it in conjunction with the Darlington amplifier included in the package (see Figure 4). There will be

FIGURE 3 — PHASE DETECTOR #2 OPERATION

a pulsed waveform on either PD or PU, depending on the phase-frequency relationship of R and V. The charge pump serves to invert one of the input waveforms (D1) and translates the voltage levels before they are applied to the loop filter. When PD is low and PU is high, Q1 will be conducting in the normal direction and Q2 will be off. Current will be flowing through Q3 and CR2; the base of Q3 will be two V_{BE} drops above ground or approximately 1.5 volts. Since both of the resistors connected to the base of Q3 are equal, the emitter of Q4 (base of Q5) will be approximately 3.0 volts. For this condition, the emitter of Q5 (DF) will be on V_{BE} below this voltage, or about 2.25 volts. The PU input to the charge pump is high (> 2.4 volts) and CR1 will be reverse biased. Therefore Q5 will be supplying current to Q6. This will tend to lower the voltage at the collector of Q7, resulting in an error signal that lowers the VCO frequency as required by a "pump down" signal.

FIGURE 4 — CHARGE PUMP OPERATION

When PU is low and PD is high, CR1 is forward biased and UF will be approximately one V_{BE} above ground (neglecting the $V_{CE(sat)}$ of the driving gate). With PD high, Q1 conducts in the reverse direction, supplying base current for Q2. While Q2 is conducting, Q4 is prevented from supplying base drive to Q5; with Q5 cut off and UF low there is no base current for Q6 and the voltage at the collector of Q7 moves up, resulting in an increase in the VCO operating frequency as required by a "pump up" signal.

If both inputs to the charge pump are high (zero phase difference), both CR1 and the base-emitter junction of Q5 are reverse biased and there is no tendency for the error voltage to change. The output of the charge pump varies between one V_{BE} and three V_{BE} as the phase difference of R and V varies from minus 2π to plus 2π . If this signal is filtered to remove the high-frequency components, the phase detector transfer function, K_{ϕ} , of approximately 0.12 volt/radian is obtained (see Figure 5).

The specified gain constant of 0.12 volt/radian may not be obtained if the amplifier/filter combination is improperly designed. As indicated previously, the charge pump delivers pump commands of about 2.25 volts on the positive swings and 0.75 volt on the negative swings for a mean no-pump value of 1.5 volts. If the filter amplifier is biased to threshold "on" at 1.5 volts, then the pump up

and down voltages have equal effects. The pump signals are established by V_{BE} s of transistors with milliamperes of current flowing. On the other hand, the transistors included for use as a filter amplifier will have very small currents flowing and will have correspondingly lower V_{BE} s — on the order of 0.6 volt each for a threshold of 1.2 volts. Any displacement of the threshold from 1.5 volts causes an increase in gain in one direction and a reduction in the other. The transistor configuration provided is hence not optimum but does allow for the use of an additional transistor to improve filter response. This addition also results in a non-symmetrical response since the threshold is now approximately 1.8 volts. The effective positive swing is limited to 0.45 volt while the negative swing below threshold can be greater than 1.0 volt. This means that the loop gain when changing from low to high and increases damping in the other direction. For type two loops this tends to increase overshoot when going from low to high and increases damping in the other direction. These problems and the selection of external filter components are intimately related to system requirements and are discussed in detail in the filter design section.

PHASE-LOCKED LOOP COMPONENTS

General

A basic phase-locked loop, when operating properly, will acquire ("lock on") an input signal, track it in frequency, and exhibit a fixed phase relationship relative to the input. In this basic loop, the output frequency will be identical to the input frequency (Figure 6). A fundamental loop consists of a phase detector, amplifier/filter, and voltage-controlled oscillator (Figure 7). It appears and acts like a unity gain feedback loop. The controlled variable is phase; any error between f_{in} and f_{out} is amplified and applied to the VCO in a corrective direction.

FIGURE 6 — BASIC PHASE-LOCKED LOOP FREQUENCY RELATIONSHIP

FIGURE 7 — FUNDAMENTAL PHASE-LOCKED LOOP

Simple phase detectors in digital phase-locked loops usually put out a series of pulses. The average value of these pulses is the "gain constant," K_{ϕ} , of the phase detector — the volts out for a given phase difference, expressed as volts/radian.

The VCO is designed so that its output frequency range is equal to or greater than the required output frequency range of the system. The ratio of change in output frequency to input control voltage is called "gain constant," K_V . If the slope of f_{out} to V_{in} is not linear (i.e., changes greater than 25%) over the expected frequency range, the curve should be piece-wise approximated and the appropriate constant applied for "best" and "worst" case analysis of loop performance.

System dynamics when in lock are determined by the amplifier/filter block. Its gain determines how much phase error exists between f_{in} and f_{out} , and filter characteristics shape the capture range and transient performance. This will be discussed in detail later.

Loop Filter

Fundamental loop characteristics such as capture range, loop bandwidth, capture time, and transient response are controlled primarily by the loop filter. The loop behavior is described by gains in each component block of Figure 8. The output to input ratio reflects a second order low pass filter in frequency response with a static gain of N :

$$\frac{\theta_O(s)}{\theta_I(s)} = \frac{K_{\phi}K_FK_V}{s + \frac{K_{\phi}K_FK_V}{N}} \quad (1)$$

where: $K_C = 1 + T_1s$

$$T_1 = R_2C \text{ and } T_2 = R_1C \text{ of Figure 4. Therefore,} \quad (2)$$

$$\frac{\theta_O(s)}{\theta_I(s)} = \frac{N(1 + T_1s)}{s^2NT_2 + T_1s + 1} \quad (3)$$

FIGURE 8 — GAIN CONSTANTS

K_{ϕ} = Phase Detector Gain (volts/radian)

K_F = Amplifier/Filter Gain

K_V = VCO Gain (radians/second/volt)

N = Integer Divisor

Both ω_n (loop bandwidth or natural frequency) and ζ (damping factor) are particularly important in the transient response to a step input of phase or frequency (Figure 9), and are defined as:

$$\omega_n = \sqrt{\frac{K_{\phi}K_V}{NT_2}} \quad (4)$$

$$\zeta = \sqrt{\frac{K_{\phi}K_V}{NT_2} \left(\frac{T_1}{2} \right)} \quad (5)$$

Using these terms in Equation 3,

$$\frac{\theta_O(s)}{\theta_I(s)} = \frac{N(1 + T_1s)}{s^2 + \frac{2\zeta\omega_n}{\omega_n^2}s + 1} \quad (6)$$

In a well defined system controlling factors such as ω_n and ζ may be chosen either from a transient basis (time domain response) or steady state frequency plot (roll-off point and peaking versus frequency). Once these two design goals are defined, synthesis of the filter is relatively straightforward.

Constants K_{ϕ} , K_V , and N are usually fixed due to other design constraints, leaving T_1 and T_2 as variables to set ω_n and ζ . Since only T_2 appears in Equation 4, it is the easiest to solve for initially.

$$T_2 = \frac{K_{\phi}K_V}{N\omega_n^2} \quad (7)$$

From Equation 5, we find

$$T_1 = \frac{2\zeta}{\omega_n} \quad (8)$$

FIGURE 9 — TYPE 2 SECOND ORDER STEP RESPONSE

Using relationships 7 and 8, actual resistor values may be computed:

$$R_1 = \frac{K\phi K_V}{N\omega_n^2 C} \quad (9)$$

$$R_2 = \frac{2\zeta}{\omega_n C} \quad (10)$$

Although fundamentally the range of R_1 and R_2 may be from several hundred to several thousand ohms, sideband considerations usually force the value of R_1 to be set first, and then R_2 and C computed.

$$C = \frac{K\phi K_V}{N\omega_n^2 R_1} \quad (11)$$

Calculation of passive components R_2 and C (in synthesizers) is complicated by incomplete information on N , which is variable, and the limits of ω_n and ζ during that variance. Equally important are changes in K_V over the output frequency range. Minimum and maximum values of ω_n and ζ can be computed from Equations 4 and 5 when the appropriate worst case numbers are known for all the factors.

Amplifier/filter gain usually determines how much phase error exists between f_{in} and f_{out} , and the filter characteristic shapes capture range and transient performance. A relatively simple, low gain amplifier may usually be used in the loop since many designs are not constrained so much by phase error as by the need to make f_{in} equal f_{out} . Unnecessarily high gains can cause

problems in linear loops when the system is out of lock if the amplifier output swing is not adequately restricted since integrating operational amplifier circuits will latch up in time and effectively open the loop.

The internal amplifier included in the MC4344/4044 may be used effectively if its limits are observed. The circuit configuration shown in Figure 10 illustrates the placement of R_1 , R_2 , C , and load resistor R_L (1 k Ω). Due to the non-infinite gain of this stage ($A_V \approx 30$) and other non-ideal characteristics, some restraint must be placed on passive component selection. Foremost is a lower limit on the value of R_2 and an upper limit on R_1 . Placed in order of priority, the recommendations are as follows: (a) $R_2 > 50 \Omega$, (b) $R_1 R_2 \leq 10$, (c) $1 \text{ k}\Omega < R_1 < 5 \text{ k}\Omega$.

FIGURE 10 — USING MC4344/4044 LOOP AMPLIFIER

Limit (c) is the most flexible and may be violated with either higher sidebands and phase error ($R_1 > 5 \text{ k}\Omega$) or lower phase detector gain ($R_1 < 1 \text{ k}\Omega$). If limit (b) is exceeded, loop bandwidth will be less than computed and may not have any similarity to the prediction. For an accurate reproduction of calculated loop characteristics one should go to an operational amplifier which has sufficient gain to make limit (b) readily satisfied. Limit (a) is very important because T_1 in Equation 5 is in reality composed of three elements:

$$T_1 = C \left(R_2 - \frac{1}{g_m} \right) \quad (12)$$

where g_m = transconductance of the common emitter amplifier.

Normally g_m is large and T_1 nearly equals $R_2 C$, but resistance values below 50Ω can force the phase-compensating "zero" to infinity or worse (into the right half plane) and give an unstable system. The problem can be circumvented to a large degree by buffering the feedback with an emitter follower (Figure 11). Inequality (a) may then be reduced by at least an order of magnitude ($R_2 > 5 \Omega$) keeping in mind that electrolytic capacitors used

PHASE-LOCKED LOOP COMPONENTS

General

A basic phase-locked loop, when operating properly, will acquire ("lock on") an input signal, track it in frequency, and exhibit a fixed phase relationship relative to the input. In this basic loop, the output frequency will be identical to the input frequency (Figure 6). A fundamental loop consists of a phase detector, amplifier/filter, and voltage-controlled oscillator (Figure 7). It appears and acts like a unity gain feedback loop. The controlled variable is phase; any error between f_{in} and f_{out} is amplified and applied to the VCO in a corrective direction.

FIGURE 6 — BASIC PHASE-LOCKED LOOP FREQUENCY RELATIONSHIP

FIGURE 7 — FUNDAMENTAL PHASE-LOCKED LOOP

Simple phase detectors in digital phase-locked loops usually put out a series of pulses. The average value of these pulses is the "gain constant," K_ϕ , of the phase detector — the volts out for a given phase difference, expressed as volts/radian.

The VCO is designed so that its output frequency range is equal to or greater than the required output frequency range of the system. The ratio of change in output frequency to input control voltage is called "gain constant," K_O . If the slope of f_{out} to V_{in} is not linear (i.e., changes greater than 25%) over the expected frequency range, the curve should be piece-wise approximated and the appropriate constant applied for "best" and "worst" case analysis of loop performance.

System dynamics when in lock are determined by the amplifier/filter block. Its gain determines how much phase error exists between f_{in} and f_{out} , and filter characteristics shape the capture range and transient performance. This will be discussed in detail later.

Loop Filter

Fundamental loop characteristics such as capture range, loop bandwidth, capture time, and transient response are controlled primarily by the loop filter. The loop behavior is described by gains in each component block of Figure 8. The output to input ratio reflects a second order low pass filter in frequency response with a static gain of N :

$$\frac{\theta_O(s)}{\theta_I(s)} = \frac{K_\phi K_F K_V}{s + \frac{K_\phi K_F K_V}{N}} \quad (1)$$

$$\text{where: } K_F = \frac{1 + T_1 s}{T_2 s} \quad (2)$$

$T_1 = R_2 C$ and $T_2 = R_1 C$ of Figure 4. Therefore,

$$\frac{\theta_O(s)}{\theta_I(s)} = \frac{N(1 + T_1 s)}{s^2 N T_2 + T_1 s + 1} \quad (3)$$

FIGURE 8 — GAIN CONSTANTS

K_ϕ = Phase Detector Gain (volts/radian)

K_F = Amplifier/Filter Gain

K_V = VCO Gain (radians/second/volt)

N = Integer Divisor

Both ω_n (loop bandwidth or natural frequency) and ζ (damping factor) are particularly important in the transient response to a step input of phase or frequency (Figure 9), and are defined as:

$$\omega_n = \sqrt{\frac{K_\phi K_V}{N T_2}} \quad (4)$$

$$\zeta = \sqrt{\frac{K_\phi K_V}{N T_2} \left(\frac{T_1}{2} \right)} \quad (5)$$

Using these terms in Equation 3,

$$\frac{\theta_O(s)}{\theta_I(s)} = \frac{N(1 + T_1 s)}{s^2 + \frac{2\zeta s}{\omega_n} + 1} \quad (6)$$

In a well defined system controlling factors such as ω_n and ζ may be chosen either from a transient basis (time domain response) or steady state frequency plot (roll-off point and peaking versus frequency). Once these two design goals are defined, synthesis of the filter is relatively straight-forward.

Constants K_ϕ , K_V , and N are usually fixed due to other design constraints, leaving T_1 and T_2 as variables to set ω_n and ζ . Since only T_2 appears in Equation 4, it is the easiest to solve for initially.

$$T_2 = \frac{K_\phi K_V}{N \omega_n^2} \quad (7)$$

From Equation 5, we find

$$T_1 = \frac{2\zeta}{\omega_n} \quad (8)$$

FIGURE 9 — TYPE 2 SECOND ORDER STEP RESPONSE

Using relationships 7 and 8, actual resistor values may be computed:

$$R_1 = \frac{K_{\phi} K_V}{N \omega_n^2 C} \quad (9)$$

$$R_2 = \frac{2\zeta}{\omega_n C} \quad (10)$$

Although fundamentally the range of R_1 and R_2 may be from several hundred to several thousand ohms, sideband considerations usually force the value of R_1 to be set first, and then R_2 and C computed.

$$C = \frac{K_{\phi} K_V}{N \omega_n^2 R_1} \quad (11)$$

Calculation of passive components R_2 and C (in synthesizers) is complicated by incomplete information on N , which is variable, and the limits of ω_n and ζ during that variance. Equally important are changes in K_V over the output frequency range. Minimum and maximum values of ω_n and ζ can be computed from Equations 4 and 5 when the appropriate worst case numbers are known for all the factors.

Amplifier/filter gain usually determines how much phase error exists between f_{in} and f_{out} , and the filter characteristic shapes capture range and transient performance. A relatively simple, low gain amplifier may usually be used in the loop since many designs are not constrained so much by phase error as by the need to make f_{in} equal f_{out} . Unnecessarily high gains can cause

problems in linear loops when the system is out of lock if the amplifier output swing is not adequately restricted since integrating operational amplifier circuits will latch up in time and effectively open the loop.

The internal amplifier included in the MC4344/4044 may be used effectively if its limits are observed. The circuit configuration shown in Figure 10 illustrates the placement of R_1 , R_2 , C , and load resistor R_L (1 k Ω). Due to the non-infinite gain of this stage ($A_V \approx 30$) and other non-ideal characteristics, some restraint must be placed on passive component selection. Foremost is a lower limit on the value of R_2 and an upper limit on R_1 . Placed in order of priority, the recommendations are as follows: (a) $R_2 > 50 \Omega$, (b) $R_1/R_2 \leq 10$, (c) $1 \text{ k}\Omega < R_1 < 5 \text{ k}\Omega$.

FIGURE 10 — USING MC4344/4044 LOOP AMPLIFIER

Limit (c) is the most flexible and may be violated with either higher sidebands and phase error ($R_1 > 5 \text{ k}\Omega$) or lower phase detector gain ($R_1 < 1 \text{ k}\Omega$). If limit (b) is exceeded, loop bandwidth will be less than computed and may not have any similarity to the prediction. For an accurate reproduction of calculated loop characteristics one should go to an operational amplifier which has sufficient gain to make limit (b) readily satisfied. Limit (a) is very important because T_1 in Equation 5 is in reality composed of three elements:

$$T_1 = C \left(R_2 - \frac{1}{g_m} \right) \quad (12)$$

where g_m = transconductance of the common emitter amplifier.

Normally g_m is large and T_1 nearly equals $R_2 C$, but resistance values below 50Ω can force the phase-compensating "zero" to infinity or worse (into the right half plane) and give an unstable system. The problem can be circumvented to a large degree by buffering the feedback with an emitter follower (Figure 11). Inequality (a) may then be reduced by at least an order of magnitude ($R_2 > 5 \Omega$) keeping in mind that electrolytic capacitors used

FIGURE 11 — AMPLIFIER CAPABLE OF HANDLING LOWER R_2 

as C may approach this value by themselves at the frequency of interest (ω_n).

Larger values of R_1 may be accommodated by either using an operational amplifier with a low bias current ($I_b < 1.0 \mu A$) as shown in Figure 12 or by buffering the internal Darlington pair with an FET (Figure 13). It is vitally important, however, that the added device be operated at zero V_{GS} . Source resistor R_4 should be adjusted for this condition (which amounts to I_{DSS} current for the FET). This insures that the overall amplifier input threshold remains at the proper potential of approximately two base-emitter drops. Use of an additional emitter follower instead of the FET and R_4 (Figure 14) gives a threshold near the upper limit of the phase detector charge pump, resulting in an extremely unsymmetrical phase detector gain in the pump up versus pump down mode. It is not unusual to note a 5:1 difference in K_ϕ for circuits having the bipolar buffer stage. If the initial design can withstand this variation in loop gain and remain stable, the approach should be considered since there are no critical adjustments as in the FET circuit.

DESIGN PROBLEMS AND THEIR SOLUTIONS

Dynamic Range

A source of trouble for all phase-locked loops, as well as most electronics is simply overload or lack of sufficient dynamic range. One limit is the amplifier output drive to the VCO. Not only must a designer note the outside limits of the dc control voltage necessary to give the output frequency range, he must also account for the worst case of overshoot expected for the system. Relatively large damping factors ($\zeta = 0.5$) can contribute significant amounts of overshoot (30%). To be prepared for the worst case output swing the amplifier should have as much margin to positive and negative limits as the expected swing itself. That is, if a two-volt swing is sufficient to give the desired output frequency excursion, there should be at least a two-volt cushion above and below maximum expected steady-state values on the control line.

This increase in range, in order to be effective, must of course be followed by an equivalent range in the VCO or there is little to be gained. Any loss in loop gain will in general cause a decrease in ζ and a consequent increase in overshoot and ringing. If the loss in gain is caused by saturation or near saturation conditions, the problem tends to accelerate towards a situation where the system settles in not only a slow but oscillator manner as well.

Loss of amplifier gain may not be due entirely to normal system damping considerations. In loops employing digital phase detectors, an additional problem is likely to appear. This is due to amplifier saturation during a step input when there is a maximum phase detector output simultaneous with a large transient overshoot. The phase detector square wave rides on top of the normal transient and may even exceed the amplifier output limits imposed above. Since the input frequency will exceed the R_2C time constant, gain K_F for these annoying pulses will be R_2/R_1 . Ordinarily this ratio will be less than 1, but some circumstances dictate a low loop gain commensurate with a fairly high ω_n . For these cases, R_2/R_1 may be higher than 10 and cause pulse-wise saturation of the amplifier. Since the dc control voltage is an average of phase detector pulses, clipping can be translated into a reduction in gain with all the "benefits" already outlined, i.e., poor settling time. An easy remedy to apply in many cases is a simple RC low pass section preceding or together with the integrator-lag section. To make transient suppression independent of amplifier response, the network may be imbedded within the input resistor R_1 (Figure 15) or be implemented by placing a feedback capacitor across R_2 (Figure 16). Besides rounding off and inhibiting pulses, these networks add an additional pole to the loop and may cause further overshoot if the cutoff frequency (ω_c) is too close to ω_n . If at all possible the cutoff point should be five to ten times ω_n . How far ω_c can be placed from ω_n depends on the input frequency relationship to ω_n since f_{in} is, after all, what is being filtered. A side benefit of this simple RC pulse "flattener" is a reduction in f_{in} sidebands around f_{out} for synthe-

sizers with $N > 1$. However, a series of RC filters is not recommended for either extended pulse suppression or sideband improvement as excess phase will begin to build up at the loop crossover ($\approx \omega_n$) and tend to cause instability. This will be discussed in more detail later.

FIGURE 15 — IMPROVED TRANSIENT SUPPRESSION
WITH $R1 - C_c$

FIGURE 16 — IMPROVED TRANSIENT SUPPRESSION
WITH $R2 - C_c$

Spurious Outputs

Although the major problem in phase-locked loop design is defining loop gain and phase margin under dynamic operating conditions, high-quality synthesizer designs also require special consideration to minimize spurious spectral components — the worst of which is reference-frequency sidebands. Requirements for good sideband suppression often conflict with other performance goals — loop dynamic behavior, suppression of VCO noise, or suppression of other in-loop noise. As a result, most synthesizer designs require compromised specifications. For a given set of components and loop dynamic conditions, reference sidebands should be predicted and checked against design specifications before any hardware is built.

Any steady-state signal on the VCO control will produce sidebands in accordance with normal FM theory. For small spurious deviations on the VCO, relative sideband-to-carrier levels can be predicted by:

$$\frac{\text{sidebands}}{\text{carrier}} \approx \frac{V_{\text{ref}} K_V}{2\omega_{\text{ref}}} \quad (13)$$

where V_{ref} = peak voltage value of spurious frequency at the VCO input.

Unwanted control line modulation can come from a variety of sources, but the most likely cause is phase detector pulse components feeding through the loop fil-

ter. Although the filter does establish loop dynamic conditions, it leaves something to be desired as a low pass section for reference frequency components.

For the usual case where ω_{ref} is higher than $1/T_2$, the K_F function amounts to a simple resistor ratio:

$$K_F(j\omega) \bigg|_{\omega = \omega_{\text{ref}}} \approx -\frac{R_2}{R_1} \quad (14)$$

By substitution of Equations 9 and 10, this signal transfer can be related to loop parameters.

$$K_F(j\omega) \bigg|_{\omega = \omega_{\text{ref}}} \approx \frac{2\zeta N\omega_n}{K_\phi K_V} = \frac{V_{\text{ref}}}{V_\phi} \quad (15)$$

where V_{ref} = peak value of reference voltage at the VCO input, and
 V_ϕ = peak value of reference frequency voltage at the phase detector output.

Sideband levels relative to reference voltage at the phase detector output can be computed by combining Equations 13 and 15:

$$\frac{\text{sideband level}}{f_{\text{out level}}} = V_\phi \left(\frac{\zeta N\omega_n}{\omega_{\text{ref}} K_\phi} \right) \quad (16)$$

From Equation 16 we find that for a given phase detector, a given value of R_1 (which determines V_ϕ), and given basic system constraints (N , f_{ref}), only ζ and ω_n remain as variables to diminish the sidebands. If there are few limits on ω_n , it may be lowered indefinitely until the desired degree of suppression is obtained. If ω_n is not arbitrary and the sidebands are still objectionable, additional filtering is indicated.

One item worthy of note is the absence of K_V in Equation 16. From Equation 15 it might be concluded that decreasing K_V would be another means for reducing spurious sidebands, but for constant values of ζ and ω_n this is not a free variable. In a given loop, varying K_V will certainly affect sideband voltage, but will also vary ζ and ω_n .

On the other hand, the choice of ω_n may well affect spectral purity near the carrier, although reference sideband levels may be quite acceptable.

In computing sideband levels, the value of V_ϕ must be determined in relation to other loop components. Residual reference frequency components at the phase detector output are related to the dc error voltage necessary to supply charge pump leakage current and amplifier bias current. From these average voltage figures, spectral components of the reference frequency and its harmonics can be computed using an approximation that the phase detector output consists of square waves τ seconds

wide repeated at t second intervals (Figure 17). A Fourier analysis can be summarized for small ratios of τ/t by:

- (1) the average voltage (V_{avg}) is $A(\tau/t)$
- (2) the peak reference voltage value (V_ϕ) is twice V_{avg} , and
- (3) the second harmonic ($2f_{ref}$) is roughly equal in amplitude to the fundamental.

By knowing the requirements for (1) due to amplifier bias and leakage currents, values for (2) and (3) are uniquely determined.

FIGURE 17 — PHASE DETECTOR OUTPUT

An example of this sideband approximation technique can be illustrated using the parameters specified for the synthesizer design included in the applications information section.

$$\begin{aligned} N_{max} &= 30 & \omega_n &= 4500 \text{ rad/s} \\ K_V &= 11.2 \times 10^6 \text{ rad/s/V} & R_1 &= 2 \text{ k}\Omega \\ K_\phi &= 0.12 \text{ V/rad} & f_{ref} &= 100 \text{ kHz} \\ \zeta &= 0.8 \end{aligned}$$

Substituting these numbers into Equation 16:

$$\frac{\text{sideband}}{f_{out}} = V_\phi \frac{(0.8)(30)(4500)}{2\pi(10^5)(0.111)} \quad (17)$$

$$= V_\phi (1.55) \quad (18)$$

The result illustrates how much reference feedthrough will affect sideband levels. If 1.0 mV peak of reference appears at the output of the phase detector, the nearest sideband will be down 56.2 dB.

If the amplifier section included in the MC4344/4044 is used, with $R_L = 1 \text{ k}\Omega$, some approximations of the value of V_ϕ can be made based on the input bias current and the value of R_1 . The phase detector must provide sufficient average voltage to supply the amplifier bias current, I_b , through R_1 ; when the bias current is about $5.0 \mu\text{A}$ and R_1 is $2 \text{ k}\Omega$, V_{avg} must be 10 mV . From the assumptions earlier concerning the Fourier transform, and with the help of Figure 18, we can see that the phase detector duty cycle will be about 1.7% ($A = 0.6 \text{ V}$), giving a fundamental (reference) of 20 mV peak. If this value for V_ϕ is substituted into Equation 18, the resulting sideband ratio represents 30 dB suppression due to this component alone.

In addition to the amplifier bias current, another factor to consider is transistor Q5 reverse leakage current I_L flowing into pin 10 of the MC4344/4044 charge pump. I_L is generally less than $1.0 \mu\text{A}$ and is no more than $5.0 \mu\text{A}$ over the temperature range. A typical design value for 25°C is $0.1 \mu\text{A}$. Both I_L and amplifier bias current I_b are

in a direction to deplete the charge on filter capacitor C. A second charge pump leakage, I_L' , attributed by diode CR1 flows out of pin 5. This current, however, is in a direction to help supply I_b and I_L and thus tends to minimize the discharge of C. Typically I_L' is much less than I_L and, since it is also in a direction to minimize discharge of the filter capacitor, it will be ignored in the following discussion. The total charge removed from C must be replaced by current supplied by the charge pump during the next up-date opportunity. This current flows through R1. To minimize the effects of I_b and I_L a relative small value of R1 should be chosen. A minimum value of $1 \text{ k}\Omega$ is a good choice.

FIGURE 18 — OUTPUT ERROR CHARACTERISTICS

DUTY CYCLE (%)	PHASE ERROR (Deg)	V_{avg} (mV)	$V_\phi(\text{peak})$ (mV)
0.1	0.36	0.6	1.2

2.0	7.2	12.0	24.0
3.0	10.8	18.0	36.0
4.0	14.4	24.0	48.0
5.0	18.0	30.0	60.0
6.0	21.6	36.0	72.0
7.0	25.2	42.0	84.0
8.0	28.8	48.0	96.0
9.0	32.4	54.0	108.0
10.0	36.0	60.0	120.0

After values for C and R_2 have been computed on the basis of loop dynamic properties, the overall sideband to f_{out} ratio computation can be simplified.

Since

$$\begin{aligned} V_\phi &= 2 V_{avg} \\ V_{avg} &= (I_b + I_L) R_1 \\ V_\phi &= 2 (I_b + I_L) R_1 \\ V_{ref} &= V_\phi \left(\frac{R_2}{R_1} \right) = 2 R_2 (I_b + I_L) \end{aligned}$$

we find that

$$\frac{\text{sideband}}{f_{out}} = \frac{V_{ref} K_V}{2\omega_{ref}} \quad (19)$$

$$\frac{\text{sideband}}{f_{out}} = \frac{2 R_2 (I_b + I_L) K_V}{2\omega_{ref}} \quad (20)$$

Equation 20 indicates that excellent suppression could be achieved if the bias and leakage terms were nulled by current summing at the amplifier input (Figure 19). This has indeed proved to be the case. Experimental results indicate that greater than 60 dB rejection can routinely

be achieved at a constant temperature. However when nulling fairly large values ($> 100 \text{ nA}$), the rejection becomes quite sensitive since leakages are inherently a function of temperature. This technique has proved useful in achieving improved system performance when used in conjunction with good circuit practice and reference filtering.

FIGURE 19 — COMPENSATING FOR BIAS AND LEAKAGE CURRENT

Additional Loop Filtering

So far, only the effects of fundamental loop dynamics on resultant sidebands have been considered. If further sideband suppression is required, additional loop filtering is indicated. However, care must be taken in placement of any low pass rolloff with regard to the loop natural frequency (ω_n). On one hand, the "corner" should be well below (lower than) ω_{ref} and yet far removed (above) from ω_n . Although no easy method for placing the roll-off point exists, a rule of thumb that usually works is:

$$\omega_c = 5\omega_n \quad (21)$$

Reference frequency suppression per pole is the ratio of ω_c to ω_{ref} .

$$\text{SdB} \approx n \cdot 20 \log_{10} \left(\frac{\omega_c}{\omega_{ref}} \right) \quad (22)$$

where n is the number of poles in the filter.

Equation 22 gives the additional loop suppression to ω_{ref} ; this number should be added to whatever suppression already exists.

For non-critical applications, simple RC networks may suffice, but if more than one section is required, loop dynamics undergo undesirable changes. Loop damping factor decreases, resulting in a high percentage of overshoot and increased ringing since passive RC sections tend to accumulate phase shift more rapidly than signal suppression and part of this excess phase subtracts from the loop phase margin. Less phase margin translates into a lower damping factor and can, in the limit, cause outright oscillation.

A suitable alternative is an active RC section, Figure 20, compatible with the existing levels and voltages. An active two pole filter (second order section) can realize a more gradual phase shift at frequencies less than the cutoff point and still get nearly equal suppression at frequencies above the cutoff point. Sections designed with a slight amount of peaking ($\zeta \approx 0.5$) show a good compromise between excess phase below cutoff (ω_c), without peaking enough to cause any danger of raising the loop gain for frequencies above ω_n . A fairly non-critical section may simply use an emitter follower as the active device

with two resistors and capacitors completing the circuit (Figure 21). This provides a -12 dB/octave (-40 dB/decade) rolloff characteristic above ω_n , though the attenuation may be more accurately determined by Equation 22. If the sideband problem persists, an additional section may be added in series with the first. No more than two sections are recommended since at that time either (1) the constraint between ω_n and ω_{ref} is too close, or (2) reference voltage is modulating the VCO from a source other than the phase detector through the loop amplifier.

FIGURE 20 — OPERATIONAL AMPLIFIER LOW PASS FILTER

1. Choose R
 $1 \text{ k}\Omega < R < 1 \text{ M}\Omega$
2. $C = \frac{0.5}{\omega_c R}$

FIGURE 21 — EMITTER FOLLOWER LOW PASS FILTER

NOTE: If $V_O \geq V_{CC} - 1.0 \text{ V}$, this stage is susceptible to power supply noise.

Operation without charge pump phase detector #1 of the MC4344/4044 can be implemented quite successfully in many applications without using the charge pump and internal darlington amplifier approach. An operational amplifier filter can be used to process the error information appearing at U1 and D1 (pins 13 and 2) directly (Figure 22). This phase detector/filter approach offers a potentially superior performing system because:

- a. Charge pump delay time is eliminated.
- b. Charge pump input signed threshold level need not be overcome before error information is obtained.

This can result in a substantial improvement in the

FIGURE 22 — TYPICAL FILTER AND SUMMING NETWORK

- 4044's transfer function linearity in the vicinity of zero phase error between the R and V inputs.
- The filter amplifier ground location can be separated from the phase detector ground.
 - An "optimum" filter amplifier input threshold of approximately two diode drops need not be established.

The filter discussions and relationships developed for integrator-log filter sections can be applied to the system of Figure 22 and the previously derived equations can be used to determine values for R1, R2 and C.

It may be desirable to split each of the R1 resistors and incorporate a capacitor to ground in a manner similar to that shown in Figure 15. This should improve transient suppression and provide integration of the U1 and D1 signals to better enable the operational amplifier to develop corrective error information from very narrow U1 and D1 pulse widths.

Phase error for the circuit in Figure 22 will result from input offset voltage in the operational amplifier, resistor mismatch and mismatch between the phase detector output states appearing at U1 and D1. Phase error can be trimmed to zero initially by adjusting either the amplifier input offset or one of the R1 resistors.

VCO Noise

Effects of noise within the VCO itself can be evaluated by considering a closed loop situation with an external noise source, e_n , introduced at the VCO (Figure 23). Resultant modulation of the VCO by error voltage, ϵ , is a second order high pass function:

$$\begin{aligned} \frac{\epsilon}{e_n} &= \frac{S^2}{S^2 + \frac{ST_1K\phi KV}{T_2N} + \frac{K\phi KV}{T_2N}} \\ &= \frac{S^2}{S^2 + 2\zeta\omega_n S + \omega_n^2} \end{aligned} \quad (23)$$

FIGURE 23 — EFFECTS OF VCO NOISE

This function has a slope of 12 dB/octave at frequencies less than ω_n (loop natural frequency), as shown in Figure 24. This means that noise components in the VCO above ω_n will pass unattenuated and those below will have some degree of suppression. Therefore choice of loop natural frequency may well rest on VCO noise quality.

FIGURE 24 — LOOP RESPONSE TO VCO NOISE

Other Spurious Responses

Spurious components appearing in the output spectrum are seldom due to reference frequency feedthrough alone. Modulation of any kind appearing on the VCO control line will cause spurious sidebands and can come in through the loop amplifier supply, bias circuitry in the control path, a translator, or even the VCO supply itself. Some VCOs have a relatively high sensitivity to power supply variation. This should be investigated and its effects considered. Problems of this nature can be minimized by operating all devices except the phase detector, charge pump, and VCO from a separate and well isolated supply. A common method uses a master supply of about 10 or 12 volts and two regulators to produce voltages for the PLL — one for all the logic (including the phase detector) and the other for all circuitry associated with the VCO control line.

Sideband and noise performance is also a function of good power supply and regulator layout. As mentioned earlier, extreme care should be exercised in isolating the control line voltage to the VCO from influences other than the phase detector. This not only means good voltage regulation but ac bypassing and adherence to good grounding techniques as well. Figure 25 shows two separate regulators and their respective loads. Resistor R_S is a small stray resistance due to a common thin ground return for both R_{L1} and R_{L2} . Any noise in R_{L2} is now reproduced (in a suppressed form) across R_{L1} . Load current from R_{L1} does not affect the voltage across R_{L2} . Even though the regulators may be quite good, they can hold V_O constant only across their outputs, not necessarily across the load (unless remote sensing is used).

FIGURE 25 — LOOP VOLTAGE REGULATION

One solution to the ground-coupled noise problem is to lay out the return path with the most sensitive regulated circuit at the farthest point from power supply entry as shown in Figure 26.

Even for regulated subcircuits, accumulated noise on the ground bus can pose major problems since although the cross currents do not produce a differential load voltage directly, they do produce essentially common mode noise on the regulators. Output differential load noise then is a function of the input regulation specification. By far the best way to sidestep the problem is to connect each subcircuit ground to the power supply entry return line as shown in Figure 27.

FIGURE 26 — REGULATOR LAYOUT

FIGURE 27 — REGULATOR GROUND CONNECTION

In Figures 25 and 27, R_{L1} and R_{L2} represent component groups in the system. The designer must insure that all ground return leads in a specific component group are returned to the common ground. Probably the most overlooked components are bypass capacitors. To minimize sidebands, extreme caution must be taken in the area immediately following the phase detector and through the VCO. A partial schematic of a typical loop amplifier and filter is shown in Figure 28 to illustrate the common grounding technique.

FIGURE 28 — PARTIAL SCHEMATIC OF LOOP AMPLIFIER AND FILTER

Bypassing in a phase-locked loop must be effective at both high frequencies and low frequencies. One capacitor in the 1.0-to-10 μF range and another between 0.01 and 0.001 μF are usually adequate. These can be effectively utilized both at the immediate circuitry (between supply and common ground) and the regulator if it is some distance away. When used at the regulator, a single electrolytic capacitor on the output and a capacitor pair at the input is most effective (Figure 29). It is important, again, to note that these bypasses go from the input/output pins to as near the regulator ground pin as possible.

FIGURE 29 — SUGGESTED BYPASSING PROCEDURE

APPLICATIONS INFORMATION

Frequency Synthesizers

The basic PLL discussed earlier is actually a special case of frequency synthesis. In that instance, $f_{\text{out}} = f_{\text{in}}$, although normally a programmable counter in the feedback loop insures the general rule that $f_{\text{out}} = Nf_{\text{in}}$ (Figure 30). In the synthesizer f_{in} is usually constant (crystal controlled) and f_{out} is changed by varying the programmable divider ($\div N$). By stepping N in integer increments, the output frequency is changed by f_{in} per increment. In com-

FIGURE 30 — PHASE-LOCKED LOOP WITH PROGRAMMABLE COUNTER

munication use, this input frequency is called the "channel spacing" or, in general, it is the reference frequency.

There is essentially no difference in loop dynamic problems between the basic PLL and synthesizers except that synthesizer designers must contend with problems peculiar to loops where N is variable and greater than 1. Also, sidebands or spectral purity usually require special attention. These and other aspects are discussed in greater detail in AN-535. The steps for a suitable synthesis procedure may be summarized as follows:

Synthesis Procedure

1. Choose input frequency. (f_{ref} = channel spacing)
2. Compute the range of digital division:

$$N_{\text{max}} = \frac{f_{\text{max}}}{f_{\text{ref}}}$$

$$N_{\text{min}} = \frac{f_{\text{min}}}{f_{\text{ref}}}$$

3. Compute needed VCO range:

$$(2f_{\text{max}} - f_{\text{min}}) < f_{\text{VCO}} < (2f_{\text{min}} - f_{\text{max}})$$

4. Choose minimum ζ from transient response plot, Figure 9. A good starting point is $\zeta = 0.5$.
5. Choose ω_n from needed response time (Figure 9):

$$\omega_n = \frac{\omega_n t}{t}$$

6. Compute C :

$$C = \frac{K_{\phi} K_V}{N_{\text{max}} \omega_n^2 R_1}$$

7. Compute R_2 :

$$R_2 = \frac{2\zeta_{\text{min}}}{\omega_n C}$$

8. Compute ζ_{max} :

$$\zeta_{\text{max}} = \zeta_{\text{min}} \sqrt{\frac{N_{\text{max}}}{N_{\text{min}}}}$$

9. Check transient response of ζ_{max} for compatibility with transient specification.
10. Compute expected sidebands:

$$\frac{\text{sideband}}{f_{\text{out}}} \approx \frac{(I_b + I_L) R_2 K_V}{\omega_{\text{ref}}} \quad (\text{A})$$

(I_L is about 100 nA at $T_J = 25^\circ\text{C}$.)

11. If step 10 yields larger sidebands than are acceptable, add a single pole at the loop amplifier by splitting R_1 and adding C_c as shown in Figure 15:

$$C_c \approx \frac{0.8}{R_1 \omega_n}$$

Added sideband suppression (dB) is:

$$\text{dB} \approx 20 \log_{10} \frac{1}{\sqrt{1 + \frac{\omega_{\text{ref}}^2}{25(\omega_n)^2}}} \quad (\text{B})$$

12. If step 11 still does not give the desired results, add a second order section at $\omega_c = 5 \omega_n$ using either the configuration of Figure 20 or 21. The expected improvement is twice that of the single pole in step 11.

$$\text{dB} \approx 40 \log_{10} \frac{1}{\sqrt{1 + \frac{\omega_{\text{ref}}^2}{25(\omega_n)^2}}} \quad (\text{C})$$

Total sideband rejection is then the total of $20 \log_{10}(\text{A}) + (\text{B}) + (\text{C})$.

Design Example (Figure 31)

Assume the following requirements:

Output frequency, $f_{\text{out}} = 2.0 \text{ MHz}$ to 3.0 MHz

Frequency steps, $f_{\text{in}} = 100 \text{ kHz}$

Lockup time between channels (to 5%) = 1.0 ms

Overshoot < 20%.

Minimum sideband suppression = -30 dB

From the steps of the synthesis procedure:

1. $f_{\text{ref}} = f_{\text{in}} = 100 \text{ kHz}$

$$N_{\text{max}} = \frac{f_{\text{max}}}{f_{\text{ref}}} = \frac{3.0 \text{ MHz}}{0.1 \text{ MHz}} = 30$$

$$N_{\text{min}} = \frac{f_{\text{min}}}{f_{\text{ref}}} = \frac{2.0 \text{ MHz}}{0.1 \text{ MHz}} = 20$$

3. VCO range:

The VCO output frequency range should extend beyond the specified minimum-maximum limits to accommodate the overshoot specification. In this instance f_{out} should be able to cover an additional 20% on either end. End limits on the VCO are:

$$f_{\text{out max}} \geq 3.0 + 0.2(1.0) = 3.2 \text{ MHz}$$

$$f_{\text{out min}} \leq 2.0 - 0.2(1.0) = 1.8 \text{ MHz}$$

This VCO range ($\approx 1.8:1$) is realizable with the MC4324/4024 voltage controlled multivibrator. From Figure 5 of the MC4324/4024 data sheet we find the required tuning capacitor value to be 120 pF and the VCO gain, K_V , typically $11 \times 10^6 \text{ rad/s/v}$.

4. From the step response curve of Figure 9, $\zeta = 0.8$ will produce a peak overshoot less than 20%.
5. Referring to Figure 9, overshoot with $\zeta = 0.8$ will settle to within 5% at $\omega_n t = 4.5$. Since the required lock-up time is 1.0 ms,

$$\omega_n = \frac{\omega_n t}{t} = \frac{4.5}{0.001} = (4.5)(10^3) \text{ rad/s}$$

6. In order to compute C , phase detector gain and R_1 must be selected. Phase detector gain, K_{ϕ} , for the MC4344/4044 is approximately 0.1 volt/radian with $R_1 = 1 \text{ k}\Omega$. Therefore,

$$C = \frac{(0.1)(11 \times 10^6)}{(30)(4.5 \times 10^3)2(10^3)} = 1.8 \mu\text{F}$$

7. At this point, R_2 can be computed:

$$R_2 = \frac{2r_{\min}}{\omega_n C} = \frac{1.6}{(4.5 \times 10^3)(1.8 \times 10^{-6})} = 200 \Omega$$

$$8. \zeta_{\max} = \zeta_{\min} \sqrt{\frac{N_{\max}}{N_{\min}}} = 0.98$$

9. Figure 9 shows that $\zeta = 0.98$ will meet the settling time requirement.

10. Sidebands may be computed for two cases: (1) with I_L (charge pump leakage current) nominal (100 nA), and (2) with I_L maximum (5.0 μA). A value of 5 μA will also be assumed for the amplifier bias current, i_b .

$$\left. \frac{\text{sideband}}{f_{\text{out}}} \right|_{\text{max}} = \frac{(10 \times 10^{-6})(200)(11 \times 10^6)}{6.28 \times 10^5} \approx 35 \times 10^{-3}$$

The sideband-to-center frequency ratio nominally will be:

$$\left. \frac{\text{sideband}}{f_{\text{out}}} \right|_{\text{nom}} = \frac{5.1}{10} \times 35 \times 10^{-3}$$

$$= 20 \log_{10}(17.85 \times 10^{-3}) \approx -35 \text{ dB}$$

If desired additional sideband filtering can be obtained as noted in steps 11 and 12.

11. By splitting R_1 and C_C , further attenuation can be gained. The magnitude of C_C is approximately:

$$C_C = \frac{0.8}{R_1 \omega_n} = \frac{0.8}{(10^3)(4.5)(10^3)} \approx 0.18 \mu\text{F}$$

Improvement in sidebands will be:

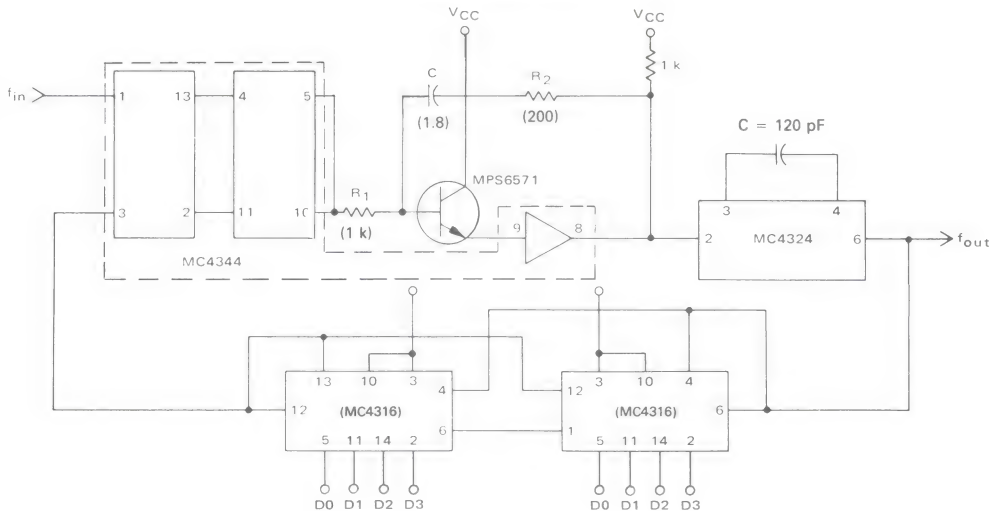

$$20 \log_{10} \frac{1}{\sqrt{1 + \frac{(2\pi \times 10^5)^2}{25(4.5 \times 10^3)^2}}} = -28 \text{ dB}$$

Nominal suppression is now -63 dB. Worst-case is 6 dB higher than nominal suppression of -57 dB. This is well within the -30 dB design requirement, step 12 is included for completeness only.

12. Attenuation of a second order filter is double that of the single order filter section described in step 11. The calculations for a second order filter indicate an additional -56 dB of sideband rejection. Figures 20 and 21 show two second order filter configurations. If R is assigned a value of 10 k Ω then C may be calculated.

$$C = \frac{0.1}{\omega_n R} = \frac{0.1}{(4.5 \times 10^3)(10^4)} = 0.0022 \mu\text{F}$$

FIGURE 31 — CIRCUIT DIAGRAM OF TYPE 2 PHASE-LOCKED LOOP

its complement, $\overline{\text{DGATE}}$, serve to initialize the circuitry and insure that the first transition of the data block (a phase transition) is ignored. The MC7493 binary counter and the G5-G12 latch generate a suitable signal for gating out G3 pulses caused by phase transitions at the end of a data cell, such as the one shown dashed in row 6.

The initial data pulse from G3 sets G12 low and is combined with DGATE in G7 to reset the counter to its zero state. Subsequent VCM clock pulses now cycle the counter and approximately one-third of the way through the next data cell the counter's full state is decoded by G11, generating a negative transition. This causes G12 to go high, removing the inhibit signal until it is again reset by the next data transition. This pulse also resets the counter, continuing the cycle and generating a positive pulse at the midpoint of each data cell as required.

Acquisition time is reduced if the loop is locked to a frequency approximately the same as the expected data rate during inter-block gaps. In Figure 32, this is achieved by operating the remaining half of the dual VCM at slightly less than the data rate and applying it to the reference input of the phase detector via the G8-G9-G10 data selector. When data appears, DGATE and $\overline{\text{DGATE}}$ cause the output of G3 to be selected as the reference input to the loop.

The loop parameters are selected as a compromise between fast acquisition and jitter-free tracking once synchronization is achieved. The resulting filter component values indicated in Figure 32 are suitable for recovering the clock from data recorded at a 120 kHz rate, such as would result in a tape system operating at 75 i.p.s. with a recording density of 1600 b.p.i. Synchronization is achieved by approximately the twenty-fourth bit time of the preamble. The relationship between system requirements and the design procedure is illustrated by the following sample calculation:

Assume a -3.0 dB loop bandwidth much less than the input data rate (≈ 120 kHz), say 10 kHz. Further, assume a damping factor of $\zeta = 0.707$. From the expression for loop bandwidth as a function of damping factor and undamped natural frequency, ω_n , calculate ω_n as:

$$\omega_{-3\text{ dB}} = \omega_n \left(1 + 2\zeta^2 + \sqrt{2 + 4\zeta^2 + 4\zeta^4} \right)^{1/2} \quad (24)$$

or for $\omega_{-3\text{ dB}} = (2\pi)10^4$ rad/s and $\zeta = 0.707$:

$$\omega_n = \frac{(2\pi)10^4}{2.06} = (3.05)10^4 \text{ rad/s}$$

As a rough check on acquisition time, assume that lockup should occur not later than half-way through a 40-bit preamble, or for twenty 8.34 μs data periods.

$$\omega_n t = (3.05)10^4(20)(8.34)10^{-6} = 5.1 \quad (26)$$

From Figure 9, the output will be within 2 to 3% of its final value for $\omega_n t \approx 5$ and $\zeta = 0.707$. The filter components are calculated by:

$$\frac{K_\phi K_V}{R_1 C N} = \omega_n^2 \quad (27)$$

and

$$\frac{K_\phi K_V R_2}{R_1 N} = 2\zeta\omega_n \quad (28)$$

$$\begin{aligned} \text{where } K_\phi &= 0.115 \text{ v/rad} \\ K_V &= (18.2) 10^6 \text{ rad/s/volt} \\ N &= 24 = \text{Feedback divider ratio} \\ \omega_n &= (3.05) 10^4 \text{ rad/s} \\ \zeta &= 0.707 \\ \frac{K_\phi K_V}{N} &= \frac{(0.115)(18.2)10^6}{24} = (8.72)10^4 \end{aligned}$$

From Equation 27:

$$R_1 C = \frac{K_\phi K_V}{N \omega_n^2} = \frac{(8.72)10^4}{(3.05)^2 10^8} = (9.34)10^{-5}$$

From Equation 28:

$$\frac{R_2}{R_1} = \frac{2\zeta\omega_n N}{K_\phi K_V} = \frac{2(0.707)(3.05)10^4}{(8.72)10^4} = 0.494 \approx \frac{1}{2}$$

Let $R_1 = 3.0 \text{ k}\Omega$; then $R_2 = 1.5 \text{ k}\Omega$ and

$$C = \frac{(9.34)10^{-5}}{(3.0)10^3} = (3.1)10^{-8}$$

or using a close standard value, use $C = 0.033 \mu\text{F}$. Now add the additional prefiltering by splitting R_1 and selecting a time constant for the additional section so that it is large with respect to $R_2 C$.

$$10(\frac{1}{2}R_1)C_C = R_2 C$$

or

$$C_C = \frac{2R_2 C}{10R_1} = \frac{2(1.5)10^3(3.3)10^{-8}}{10(3.0)10^3} = 3300 \text{ pF}$$

MOTOROLA

MC12002

ANALOG MIXER

The MC12002 is a double balanced analog mixer, including an input amplifier feeding the mixer carrier port and a temperature compensated bias regulator. The input circuits for both the amplifier and mixer are differential amplifier circuits. The on-chip regulator provides all of the required biasing.

This circuit is designed for use as a balanced mixer in high-frequency wide-band circuits. Other typical applications include suppressed carrier and amplitude modulation, synchronous AM detection, FM detection, phase detection, and frequency doubling, at frequencies up to UHF.

- 310 Milliwatts (Typ)

*When using a +5.0 V supply, apply +5.0 V to Pin 1 (V_{CCQ}), Pin 6 (MTTL V_{CC}), Pin 16 (V_{CC}), and ground Pin 8 (V_{EE}). When using -5.2 V supply, ground Pin 1 (V_{CCQ}), Pin 6 (MTTL V_{CC}), and Pin 16 (V_{CC}) and apply -5.2 V to Pin 8 (V_{EE}). If the translator is not required, Pin 6 may be left open to conserve dc power drain.

The State of the Enable is important only for the positive Clock Transition when the counter is in state 1100.

APPLICATIONS INFORMATION

The primary application of these devices is as a high-speed variable modulus prescaler in the divide by N section of a phase-locked loop synthesizer used as the local oscillator of two-way radios. The theory and advantages of variable modulus prescaling, along with typical applications, are covered in Motorola's "Electronic Tuning Address Systems" (SG72).

Proper VHF termination techniques should be followed when the clock is separated from the prescaler by any appreciable distance.

In their basic form, these devices will divide by 5/6, 8/9, or 10/11. Division by 5, 8, or 10 occurs when any one or all of the five gate inputs E1 through E5 are high. Division by 6, 9, or 11 occurs when all inputs E1 through E5 are low. (Unconnected MTTL inputs are normally high, unconnected MECL inputs are normally low). With the addition of extra parts, many different division configurations may be obtained (20/21, 40/41, 50/51, 100/101, etc.) A few of the many configurations are shown below, only for the MC12013

COUNTER CONTROL LOGIC

The MC12014 monolithic counter control logic unit is designed for use with the MC12013 Two-Modulus Prescaler and the MC4016 Programmable Counter to accomplish direct high-frequency programming. The MC12014 consists of a zero detector which controls the modulus of the MC12013, and an early decode function which controls the MC4016. The early decode feature also increases the useful frequency range of the MC4016 from 8.0 MHz to 25 MHz.

SWITCHING TIME TEST CIRCUIT AND WAVEFORMS

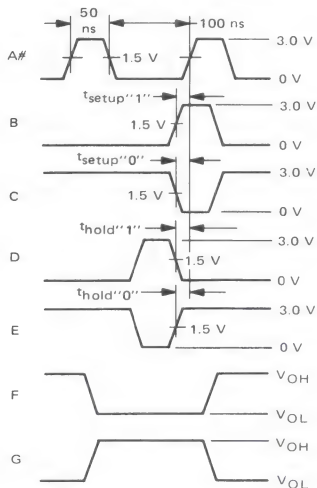

Two pulse generators are required and must be slaved together to provide the waveforms shown.

$C_T = 15$ pF = total parasitic capacitance, which includes probe, wiring, and load capacitances.

The coax delays from input to scope and output to scope must be matched. The scope must be terminated in 50-ohm impedance. The 950-ohm resistor and the scope termination impedance constitute a 20:1 attenuator probe. Coax shall be CT-070-50 or equivalent.

SETUP AND HOLD TIMES

PROPAGATION DELAY TIMES

#Pulse A (f_{in}) used with all tests.

APPLICATIONS INFORMATION

The MC12014 Counter Control Logic incorporates two features for enhancing operation of the MC4016/4018 Programmable Counters.¹ Maximum operating frequency of the counters is limited by the time required for re-programming at the end of each count-down cycle. Operation can be extended to approximately 25 MHz by using the "early decode" feature included in the MC12014. The appropriate connections are shown in Figure 2. Only three counter stages are shown; however, up to eight stages can be satisfactorily cascaded. Note the following differences between this and the non-extended method: the counter gate inputs are not connected to the input clock; all parallel enables are connected to the \bar{Q} output (f_{out}) of a type D flip-flop formed by gates G2 through G7 in the MC12014 package; the bus terminal of the least significant stage is grounded; all other bus terminals and one internal resistor, R, are connected together and serve as a data input, B1, to the flip-flop. Four additional data inputs, $\bar{P}0$ through $\bar{P}3$, serve to decode the "two" state of the least significant counter stage. Circuit operation is illustrated in waveforms of Figure 2, where the timing for the end of a count-down cycle is shown in expanded form. The counter parallel inputs are assumed to have $N = 245$ programmed. Timing is not shown for the third stage since it has already been counted down to the all zero state. As the next-to-least significant stage reaches zero, the common bus line goes high. Count down of the least significant stage continues until the "two" state is reached, causing the remaining data inputs to the flip-flop to go high. The next-to-last clock pulse of the cycle then triggers the flip-flop \bar{Q} output low. This takes the parallel enables of all three counter stages low, resetting

the programmed data to the outputs. The next input pulse clocks \bar{Q} back to the high state since the data inputs to the flip-flop are no longer all high. The resulting negative output pulse at f_{out} is one input clock period in duration. Note that division by N equal to 001 or 002 is not available using this method.

The frequency synthesizer shown in Figure 8 requires that the programmable counters be quickly stopped after reaching their terminal (zero) count. This can be simply accomplished by taking the master reset of all stages low at the appropriate time. The bus output of the counters could be used for this function since a transition there signals the end of a count-down sequence. However, due to the relatively long delay between the last positive clock transition and the bus transition a faster method is required in this application.

The "zero detection" feature of the MC12014 provides a convenient means of implementing a faster method. Gates G12 through G19 form a latch whose output goes high if B2 is high and low logic levels are applied to the Z0 thru Z3 inputs. When once set to a one by appropriate input conditions, the output of G19 remains high until it is reset by the circuit comprised of gates G8 through G11. Note that since the required information is stored, the counter can be allowed to continue cycling.

The G8-G11 circuit monitors the G7 output of the "early decode" type D flip-flop. When the counter stage connected to the $\bar{P}0$ thru $\bar{P}3$ inputs has counted down to its two state the output of G7 goes high; this enables the G8-G11 circuitry and the next positive clock transition causes the output of G11 to go high, resetting the output of G19 to zero.

FIGURE 1 — TYPICAL FREQUENCY SYNTHESIZER APPLICATION

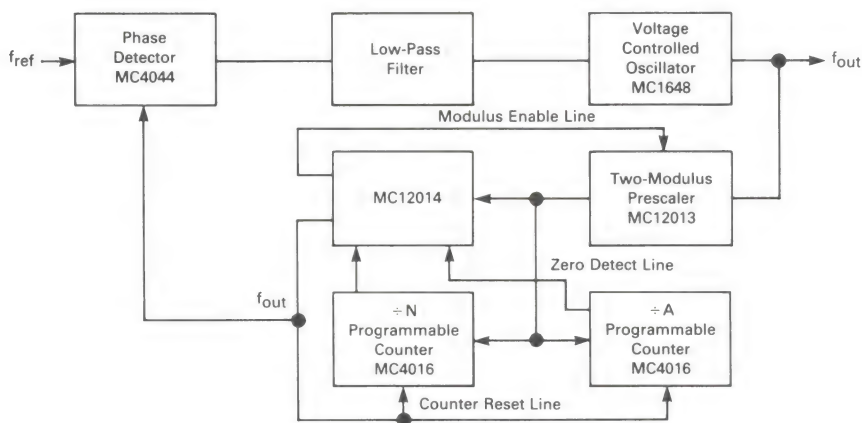

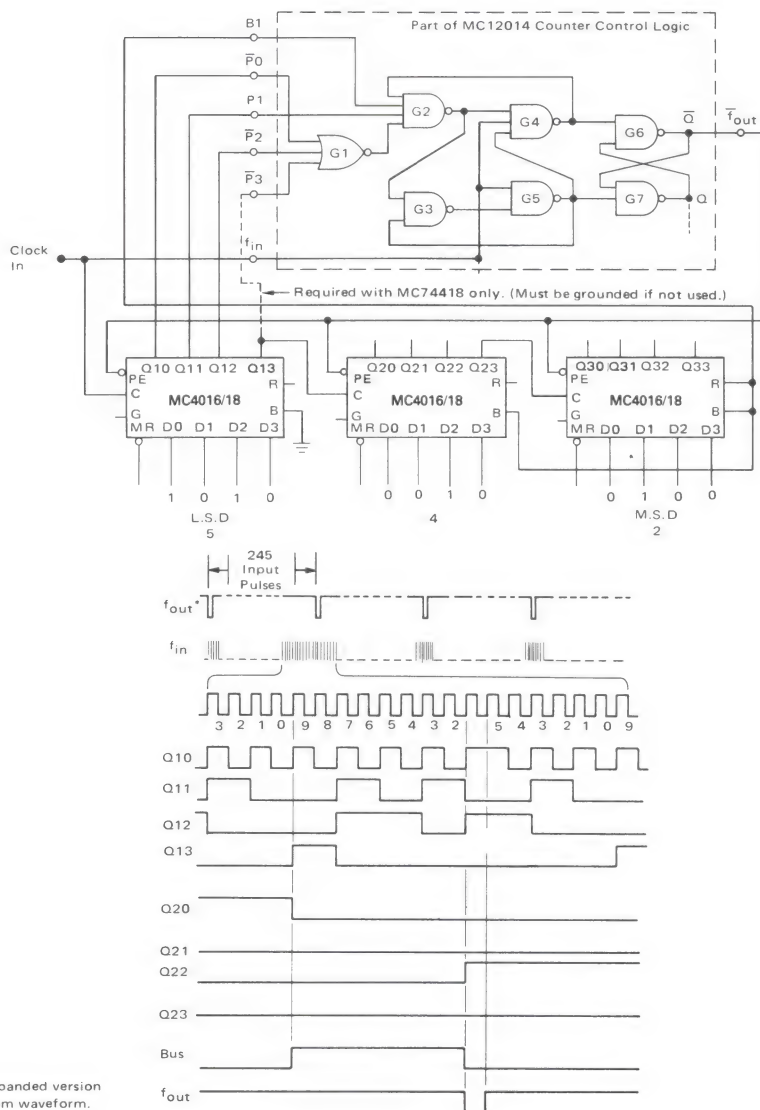

FIGURE 2 — INCREASING THE OPERATING RANGE OF MC74416/74418 PROGRAMMABLE COUNTERS USING MC12014

1 See the MC54416/54418 data sheet for additional information.

Operation of the Counter Control Logic can be further clarified by considering a typical system application for programmable counters illustrated in the frequency synthesizer shown in Figure 3. There the counter provides a means of digitally selecting some integral multiple of a stable reference frequency. The circuit phase locks the output, f_{VCO} , of a voltage controlled oscillator to a reference frequency, f_{ref} .² Circuit operation is such that $f_{VCO} = Nf_{ref}$, where N is the divider ratio of the feedback counter, permitting frequency selection by means of thumbwheel switches.

In many synthesizer applications the VCO is operated at VHF frequencies too high for direct division by TTL counters. In these cases the VCO output is usually prescaled by using a suitable fixed divide-by-M ECL circuit as

shown in Figure 4. For this configuration, $f_{VCO} = NMf_{ref}$, where N is variable (programmable) and M is fixed. Design of the optimum loop filter requires that the input reference frequency be as high as possible where the upper limit is established by the required channel spacing. Since $f_{VCO} = Nf_{ref}$ in the non-prescaled case, if N is changed by one, the VCO output changes by f_{ref} , or the synthesizer channel spacing is just equal to f_{ref} . When the prescaler is used as in Figure 4, $f_{VCO} = NMf_{ref}$, and a change of one in N results in the VCO changing by Mf_{ref} , i.e., if f_{ref} is set equal to the minimum permissible channel spacing as is desirable, then only every M channels in a given band can be selected. One solution is to set $f_{ref} = \text{channel spacing}/M$ but this leads to more stringent loop filter requirements.

FIGURE 3 — TTL PHASE-LOCKED LOOP

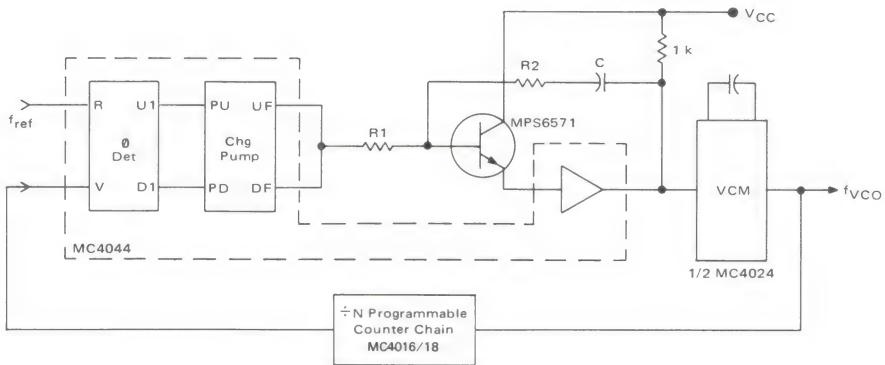

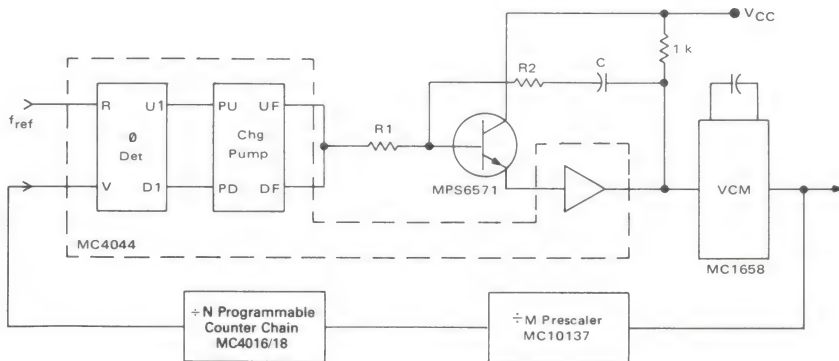

FIGURE 4 — TTL-MECL PHASE-LOCKED LOOP

2 See Motorola Application Notes AN-535, AN-532, and the MC4344/4044 Data Sheet for detailed explanation of over-all circuit operation.

An alternate approach that avoids this problem is provided by the counter configuration shown in Figure 5. It too uses a prescaler ahead of a programmable counter, however the modulus of the prescaler is now controlled by a third counter, causing it to alternate between M and $M + 1$. Operation is best explained by assuming that all three counters have been set for the beginning of a cycle: the prescaler for division by $(M + 1)$, the modulus control counter for division by N_{mc} , and the programmable counter for division by N_{pc} . The prescaler will divide by $(M + 1)$ until the modulus control counter has counted down to zero; at this time, the all zero state is detected and causes the prescaler to divide by M until the programmable counter has also counted down to zero. When this occurs, a cycle is complete and each counter is reset to its original modulus in readiness for the next cycle.

To determine the relationship between f_{out} and f_{in} , let T_1 be the time required for the modulus control counter to reach its terminal count and let T_2 be the remainder of one cycle. That is, T_2 is the time between terminal count in the modulus control counter and terminal count in the programmable counter. When the modulus control counter reaches zero, N_{mc} pulses will have entered it at a rate given by $f_{in}/(M + 1)$ pulses/second or T_2 is:

$$T_1 = \frac{(M + 1)}{f_{in}} \cdot N_{mc} \quad (1)$$

At this time, N_{mc} pulses have also entered the programmable counter and it will reach its terminal count after $(N_{pc} - N_{mc})$ more pulses have entered. The rate of entry is now f_{in}/M pulses/second since the prescaler is now dividing by M . From this T_2 is given by:

$$T_2 = \frac{M}{f_{in}} \cdot (N_{pc} - N_{mc}) \quad (2)$$

$$\text{Since } f = \frac{1}{T}:$$

$$f_{out} = \frac{1}{T_{total}} = \frac{1}{T_1 + T_2} = \frac{1}{\frac{(M+1)N_{mc}}{f_{in}} + \frac{M(N_{pc} - N_{mc})}{f_{in}}} \quad (3)$$

$$\begin{aligned} f_{out} &= \frac{f_{in}}{(M+1)N_{mc} + M(N_{pc} - N_{mc})} \\ &= \frac{f_{in}}{MN_{mc} + N_{mc} + MN_{pc} - MN_{mc}} \\ &= \frac{f_{in}}{MN_{pc} + N_{mc}} \end{aligned}$$

In terms of the synthesizer application, $f_{VCO} = (MN_{pc} + N_{mc}) f_{ref}$ and channels can be selected every f_{ref} by letting N_{pc} and N_{mc} take on suitable integer values, including zero.

FIGURE 5 — FEEDBACK COUNTERS WITH DUAL MODULUS PRESCALER

A simplified example of this technique is shown in Figure 6. The MC12013 Dual Modulus Prescaler divides by either 10 or 11 when connected as shown in Figure 6. If the E3 and E4 Enable inputs are high at the start of a prescaler cycle, division by 10 results; if the Enable inputs are low at the beginning of the cycle, division by 11 results. The zero detection circuitry of the MC12014 Counter Control Logic is connected to monitor the outputs of the modulus control counter; this provides a suitable enable signal at E0 as the modulus control counter reaches its terminal (zero) count. The remainder of the MC12014 is connected to extend the operating frequency of the programmable counter chain. Appropriate waveforms for division by 43 are shown in Figure 7a.

The beginning of the timing diagram indicates circuit status just prior to the end of a countdown cycle, i.e., the modulus control counter has been counted down to one and the programmable counter is in the two state. The next positive transition from the prescaler (f_1 in the timing diagram) then initiates the following sequence of events. Since the two state of the programmable counter enables the early decode circuitry in the MC12014, the positive f_1 transition causes f_{out} to go low. Since f_{out} is connected to the Parallel Enables of all the MC4016 counters this low signal will re-program the counters in readiness for another cycle. However, due to the propagation time through the decode circuitry, the programmable and modulus control counters are briefly decremented to one and zero, respectively, before re-programming occurs. The momentary zero state of the modulus control counter is detected, setting E_0 of the MC12014 high, enabling the MC12013 for division by ten during its next cycle. After eleven more f_{in} pulses (E_0 went high after the beginning of the prescaler cycle and so doesn't change the modulus until the next prescaler cycle), f_1 again goes high, causing f_{out} to return to the one state. This releases the Parallel Enables and simultaneously resets E_0 to zero. However, since E_0 was high when the current prescaler cycle began, the next positive f_1 transition occurs only ten f_{in} pulses later. Subsequent f_1 transitions now decrement the MC4016 counters down through another cycle with the prescaler dividing by eleven. From the waveforms, $11 + 10 + 11 + 11 = 43$ input pulses occur for each output pulse.

The required divider range, 4800 to 5933, is obtained in the following manner: the MC12013 Dual Modulus Prescaler is connected in the divide by 10/11 mode; the modulus control counter uses two MC4016 stages with N_{mc} ranging from 00 to 99, establishing the two least significant digits of N_T. The remaining two digits of N_T are obtained from a three stage programmable counter generating N_{pc}. The least significant stage of the N_{pc} counter is fixed programmed to zero. The required programming for all remaining stages is derived from four channel selector BCD thumbwheel switches. The relationship between N_T and the counters is given by N_T = MN_{pc} + N_{mc}; for a typical channel, say 144.33 MHz, N_T = 4811 requires that M = 10, N_{pc} = 480, and N_{mc} = 11, or N_T = (10)(480) + 11 = 4811.

A general problem associated with synthesizer design arises from the fact that there is not always a one-to-one correspondence between the code provided by the channel selector switches and the code required for proper programming of the counters. For instance, in the example above where 144.33 MHz was selected, the channel selector switches are set to 44.33 while the required divider ratio is 4811. There are numerous solutions for a given translation requirement, however the method shown here using read only memories offers a straight-

The required divider range, 4800 to 5933, is obtained in the following manner: the MC12013 Dual Modulus Prescaler is connected in the divide by 10/11 mode; the modulus control counter uses two MC4016 stages with N_{mc} ranging from 00 to 99, establishing the two least significant digits of N_T . The remaining two digits of N_T are obtained from a three stage programmable counter generating N_{pc} . The least significant stage of the N_{pc} counter is fixed programmed to zero. The required programming for all remaining stages is derived from four channel selector BCD thumbwheel switches. The relationship between N_T and the counters is given by $N_T = MN_{pc} + N_{mc}$; for a typical channel, say 144.33 MHz, $N_T = 4811$ requires that $M = 10$, $N_{pc} = 480$, and $N_{mc} = 11$, or $N_T = (10)(480) + 11 = 4811$.

A general problem associated with synthesizer design arises from the fact that there is not always a one-to-one correspondence between the code provided by the channel selector switches and the code required for proper programming of the counters. For instance, in the example above where 144.33 MHz was selected, the channel selector switches are set to 44.33 while the required divider ratio is 4811. There are numerous solutions for a given translation requirement, however the method shown here using read only memories offers a straightforward design method. While field programmable read only memories (PROMs) are shown, they would normally be used only during development; suitable fixed ROMs are more economical in production quantities. The design procedure for the code conversion is illustrated in Figure 9. The required programming for the two most

significant digits of N_{pc} is shown versus the code provided by switches #1 and #2 of the channel selector. If the four outputs of switch #2 and the two least significant outputs of switch #1 are regarded as address bits A0 through A5 for a 64 x 8 TTL PROM, a memory location can be associated with each switch setting. The required N_{pc} programming for each switch setting is then set into the appropriate memory location by the user. In Figure 9, the required programming has been transferred into a truth table to be used while programming the PROM. A similar result for the N_{mc} programming is shown in Figure 10. Note that the PROM shown, N_{mc} PROM #1, selects only N_{mc} numbers 00 through 33. This means that the synthesizer as shown in Figure 8 selects only the adjacent channels in a one megahertz slice of the total band. The frequency ranges that can be selected using N_{mc} PROM #1 are summarized in Figure 10. For other ranges, N_{mc} PROM #1 must be replaced by one of two additional PROMs required for generating the remaining N_{mc} numbers. Appropriate truth tables along with the ranges they can be used with are shown in Figures 11 and 12.

MOTOROLA

MC12015 MC12016 MC12017

LOW-POWER TWO-MODULUS PRESCALER

The MC12015, MC12016 and MC12017 are two-modulus prescalers which will divide by 32 and 33, 40 and 41, and 64 and 65 respectively. An internal regulator is provided to allow these devices to be used over a wide range of power-supply voltages. The devices may be operated by applying a supply voltage of 5.0 Vdc \pm 10% at pin 7 or by applying an unregulated voltage source from 5.5 Vdc to 9.5 Vdc to pin 8.

- 225 MHz Toggle Frequency
- Low-Power — 7.5 mA Max at 6.8 V
- Control Input and Output are Compatible with Standard CMOS
- Connecting Pins 2 and 3 Allows Driving One TTL Load
- Supply Voltage 4.5 V to 9.5 V

MOTOROLA

Advance Information

1.1 GHz LOW-POWER TWO-MODULUS PRESCALER

The MC12022A can be used with CMOS synthesizers requiring positive edges to trigger internal counters such as Motorola's MC145xxx series in a PLL to provide tuning signals up to 1.1 GHz in programmable frequency steps.

The MC12022B can be used with CMOS synthesizers requiring negative edges to trigger internal counters such as Fujitsu's MB87001.

A Divide Ratio Control (SW) permits selection of a 64/65 or 128/129 divide ratio as desired.

The Modulus Control (MC) selects the proper divide number after SW has been biased to select the desired divide ratio.

- 1.1 GHz Toggle Frequency
- The MC12022B is Pin and Functionally Compatible with Fujitsu Device MB501L
- The MC12022 has Lower Power Supply Current than the MB501L
 - 10 mA Maximum, -40°C to $+85^{\circ}\text{C}$, $V_{CC} = 4.5\text{--}5.5\text{ Vdc}$ versus 14 mA Maximum, 25°C , $V_{CC} = 5.0\text{ Vdc}$
- Shorter Setup Time (t_{SET}) than the MB501L
 - 16 nsec versus 26 nsec Maximum
- Supply Voltage $5.0\text{ Vdc} \pm 10\%$
- Low-Power 7.5 mA Typical
- Modulus Control Input Level is Compatible with Standard CMOS and TTL. Maximum Input Voltage should be Limited to 5.5 Vdc.

PRESCALER PIN ASSIGNMENT

(Top View)

Pin assignment is for Dual-in-line Package.
For PLCC pin assignment, see tables on page 1-31.

Note 1:

For positive edge triggered synthesizers,
order the MC12022A.

For negative edge triggered synthesizers,
order the MC12022B.

FUNCTION TABLE

SW	MC	Divide Ratio
H	H	64
H	L	65
L	H	128
L	L	129

Note: SW: H = V_{CC} , L = open
MC: H = 2.0 V to V_{CC}
L = Gnd to 0.8 V

LOGIC DIAGRAM

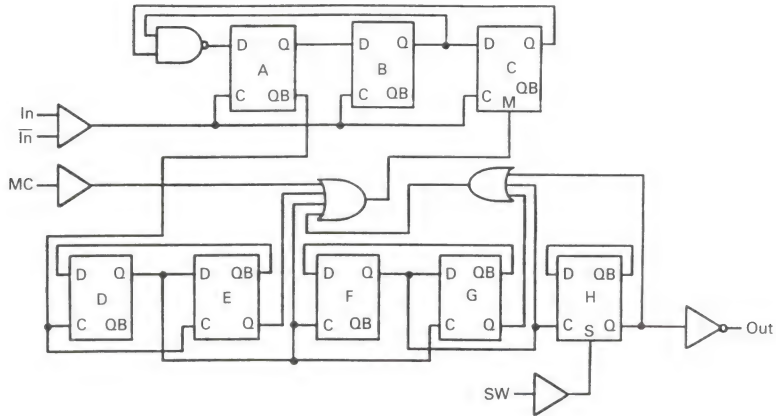

FIGURE 1 — MODULUS SETUP TIME

Modulus setup time MC to out is the MC setup or MC release plus the prop. delay.

MOTOROLA

MC12023

÷ 64, 225 MHz, LOW-POWER PRESCALER

The MC12023 is a new member of Motorola's PLL family. The MC12023 is a prescaler which will divide by 64. This device may be operated over a wide range of supply voltages (3.2 to 5.5 V). Because of this range of supply voltages the MC12023 is very suitable for hand-held, battery-operated devices.

- 225 MHz Toggle Frequency
- Low Power—4.8 mA Maximum at 5.5 V
- Operating Supply Voltage — 3.2 V to 5.5 V
- Connecting Pins 2 and 3 Allows Driving One TTL Load

MC12040

PHASE-FREQUENCY DETECTOR

The MC12040 is a phase-frequency detector intended for use in systems requiring zero phase and frequency difference at lock. In combination with a voltage controlled oscillator (such as the MC1648), it is useful in a broad range of phase-locked loop applications. Operation of this device is identical to that of Phase Detector #1 of the MC4044. A discussion of the theory of operation and applications information is given on the MC4344/4044 data sheet.

Operating Frequency = 80 MHz typical

AC TESTS

NOTES:

1. All input and output cables to the scope are equal lengths of 50 Ω coaxial cable.
2. Unused input and outputs are connected to a 50 Ω resistor to ground.
3. The device under test must be preconditioned before performing the ac tests. Preconditioning may be accomplished by applying pulse generator 1 for a minimum of two pulses prior to pulse generator 2. The device must be preconditioned again when inputs to pins 6 and 9 are interchanged. The same technique applies.

APPLICATIONS INFORMATION

The MC12040 is a logic network designed for use as a phase comparator for MECL-compatible input signals. It determines the "lead" or "lag" phase relationship and the time difference between the leading edges of the waveforms. Since these edges occur only once per cycle, the detector has a range of $\pm 2\pi$ radians.

Operation of the device may be illustrated by assuming two waveforms, R and V (Figure 1), of the same frequency but differing in phase. If the logic had established by past history that R was leading V, the U output of the detector (pin 4) would produce a positive pulse width equal to the phase difference and the D output (pin 11) would simply remain low.

On the other hand, it is also possible that V was leading R (Figure 1), giving rise to a positive pulse on the D output and a constant low level on the U output pin. Both outputs for the sample condition are valid since the determination of lead or lag is dependent on past edge crossing and initial conditions at start-up. A stable phase-locked loop will result from either condition.

Phase error information is contained in the output duty cycle — that is, the ratio of the output pulse width to total period. By integrating or low-pass filtering the outputs of the detector and shifting the level to accommodate ECL swings, usable analog information for the voltage-controlled oscillator can be developed. A circuit useful for this function is shown in Figure 2.

Proper level shifting is accomplished by differentially

driving the operational amplifier from the normally high outputs of the phase detector (\bar{U} and \bar{D}). Using this technique the quiescent differential voltage to the operational amplifier is zero (assuming matched "1" levels from the phase detector). The \bar{U} and \bar{D} outputs are then used to pass along phase information to the operational amplifier. Phase error summing is accomplished through resistors R1 connected to the inputs of the operational amplifier. Some R-C filtering imbedded within the input network (Figure 2) may be very beneficial since the very narrow correctional pulses of the MC12040 would not normally be integrated by the amplifier. General design guides for calculating R1, R2, and C are included in the MC4044 data sheet. Phase detector gain for this configuration is approximately 0.16 volts/radian.

System phase error stems from input offset voltage in the operational amplifier, mismatching of nominally equal resistors, and mismatching of phase detector "high" states between the outputs used for threshold setting and phase measuring. All these effects are reflected in the gain constant. For example, a 16 mV offset voltage in the amplifier would cause an error of $0.016/0.16 = 0.1$ radian or 5.7 degrees of error. Phase error can be trimmed to zero initially by trimming either input offset or one of the threshold resistors (R1 in Figure 2). Phase error over temperature depends on how much the offsetting parameters drift.

MOTOROLA

MC12060 MC12061

CRYSTAL OSCILLATOR

The MC12060 and MC12061 are for use with an external crystal to form a crystal controlled oscillator. In addition to the fundamental series mode crystal, two bypass capacitors are required (plus usual power supply pin bypass capacitors). Translators are provided internally for MECL and TTL outputs.

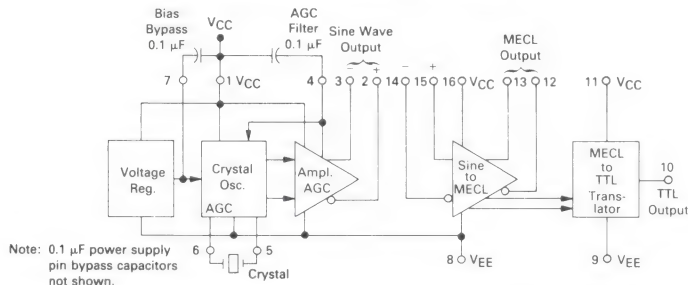

- Frequency Range = 100 kHz to 2.0 MHz for MC12060
2.0 MHz to 20 MHz for MC12061
- Temperature Range = 0°C to +70°C for MC12060/061
- Single Supply Operation: +5.0 Vdc or -5.2 Vdc
- Three Outputs Available:
 1. Complementary Sine Wave (600 mVp-p typ)
 2. Complementary MECL
 3. Single Ended TTL

* R_S MC12060 = 3 k Ω

MC12061 = 15 k Ω is inserted only for test purposes. When used with the above specified crystal, it guarantees oscillation with any crystal which has an equivalent series resistance ≤ 155 Ω for MC12061 and ≤ 4 k Ω for MC12060

R_P : will improve start up problems value: 200–500 Ω

OPERATING CHARACTERISTICS

The MC12061 and MC12060 consist of three basic sections: an oscillator with AGC and two translators (Figure 1). Buffered complementary sine wave outputs are available from the oscillator section. The translators convert these sine wave outputs to levels compatible with MECL and/or TTL.

Series mode crystals should be used with the oscillator. If it is necessary or desirable to adjust the crystal frequency, a reactive element can be inserted in series with the crystal — an inductor to lower the frequency or a capacitor to raise it. When such an adjustment is necessary, it is recommended that the crystal be specified slightly lower in frequency and a series trimmer capacitor be added to bring the oscillator back on frequency. As the oscillator frequency is changed from the natural resonance of the crystal, more and more dependence is placed on the external reactance, and temperature drift of the trimming components then affects overall oscillator performance.

The MC12061 and MC12060 are designed to operate from a single supply — either +5.0 Vdc or -5.2 Vdc. Although each translator has separate V_{CC} and V_{EE} supply pins, the circuit is NOT designed to operate from both voltage levels at the same time. The separate V_{EE} pin from the TTL translator helps minimize transient disturbance. If neither translator is being used, all unused pins (9 thru 16) should be connected to V_{EE} (pin 8). With the translators not powered, supply current drain is typically reduced from 42 mA to 23 mA for the MC12061, and 35 mA to 16 mA for the MC12060.

Frequency Stability

Output frequency of different oscillator circuits (of a given device type number) will vary somewhat when used with a given test setup, however the variation should be within approximately $\pm 0.001\%$ from unit to unit.

Frequency variations with temperature (independent of the crystal, which is held at 25°C) are small — about -0.08 ppm/°C for MC12061 operating at 8.0 MHz, and about -0.16 ppm/°C for MC12060 operating at 1.0 MHz (see Figure 8).

Signal Characteristics

The sine wave outputs at either pin 2 or pin 3 will typically range from 800 mVp-p (no load) to 500 mVp-p (120 ohm ac load). Approximately 500 mVp-p can be provided across 50 ohms by slightly increasing the dc current in the output buffer by the addition of an external resistor (680 ohms) from pin 2 or 3 to ground, as shown in Figure 9. Frequency drift is typically less than 0.0003% when going from a high-impedance load (1 megohm, 15 pF) to the 50 ohm load of Figure 9. The dc voltage level at pin 2 or 3 is nominally 3.5 Vdc with $V_{CC} = +5.0$ Vdc.

Harmonic distortion content in the sine wave outputs is crystal as well as circuit dependent. The largest harmonic (third) will usually be at least 15 dB down from the fundamental. The harmonic content is approxi-

mately load independent except that the higher harmonic levels (greater than the fifth) are increased when the MECL translator is being driven.

Typically, the MECL outputs (pins 12 and 13) will drive up to five gates, as defined in Figure 10, and the TTL output (pin 10) will drive up to ten gates, as defined in Figure 11.

Noise Characteristics

Noise level evaluation of the sine wave outputs using the circuit of Figure 12, with operation at 1.0 MHz for MC12060 or 9.0 MHz for MC12061, indicates the following characteristics:

1. Noise floor (200 kHz from oscillator center frequency) is approximately -122 dB when referenced to a 1.0 Hz bandwidth. Noise floor is not sensitive to load conditions and/or translator operation.
2. Close-in noise (100 Hz from oscillator center frequency) is approximately -88 dB when referenced to a 1.0 Hz bandwidth.

MC12071

**DO NOT USE
FOR NEW DESIGNS**

HIGH-SPEED PRESCALER

The MC12071 is a high-speed prescaler designed for use in communications and instrumentation systems. In the UHF mode, it performs division by 256, and divides by 64 in the VHF mode.

A bandswitch mode control line selects the mode of operation between the UHF and VHF input pins.

UHF operation is selected by applying a high-level (logical 1) to the bandswitch input. A low-level (logical 0) is applied to the bandswitch input to obtain the VHF mode. An internal amplifier/multiplexer is used to isolate both inputs, amplify the input signal, and improve sensitivity.

Inputs are designed for ac-coupled sine wave signals, but can be dc-coupled if proper bias levels are maintained. Normally used single-ended, the inputs can also be operated with complementary input signals if required.

Circuit outputs are complementary emitter-follower type which can drive a 33-pF or equivalent load. Maintaining a balanced load and controlling rise and fall times will reduce harmonic outputs.

TYPICAL APPLICATIONS

- CATV Converters
- Digital frequency synthesizers for:
VHF/UHF receivers
Instrumentation
Satellite communications
- High-frequency divider for:
Frequency counters (UHF)
Timers (UHF)
High-Speed computers
SHF, second IF local-oscillator injection
Frequency standards
PCM communications
Radar ranging systems
Satellite communications
- High-frequency up-converters

MAXIMUM RATING

Rating	Symbol	Value	Unit
Power Supply Voltage	V_{CC}	7.0	Vdc
Operating Power Supply Voltage	V_{CC}	$5.0 \pm 10\%$	Vdc
Bandswitch Voltage	V_{BH}	20	Vdc
Input Voltage	V_{in}	0.5	V _{RMS}
Operating Temperature Range	T_A	0 to +70	°C
Storage Temperature Range	T_{stg}	-55 to +125	°C
Junction Temperature	T_J	150	°C

Ratings above which device life may be impaired.

ELECTRICAL CHARACTERISTICS ($V_{CC} = 5.0$ V, $T_A = 0^\circ\text{C}$ to $+70^\circ\text{C}$)

Characteristics	Symbol	Min	Typ	Max	Unit
STATIC					
Supply Current (Pins 1 & 2)	I_{CC}	30	60	90	mA
Bandswitch Voltage, Low	V_{BL}	0	—	0.8	Vdc
High	V_{BH}	2.4	—	20	Vdc
Bandswitch current 0 to 0.8 V	I_{BL}	-0.5	—	—	mA
2.4 to 20 V	I_{BH}	—	—	0.5	mA
Output Voltage, High	V_{OH}	—	4.2	—	Vdc
Output Voltage, Low	V_{OL}	—	3.0	—	Vdc
DYNAMIC (See Fig. 2)					
UHF Input Sensitivity Range (See note)	UHF_{in}	60	—	*200	mVRMS
$f_{in} = 450$ to 950 MHz, V_{BH}		150	—	500	
$f_{in} = 80$ to 450 MHz, V_{BL}					
VHF Input Sensitivity Range (See note)	VHF_{in}	40	—	500	mVRMS
$f_{in} = 90$ to 275 MHz, V_{BL}					
Output Voltage	V_{out}	0.65	1.2	1.6	Vp-p
Output Rise or Fall Time	t_r, t_f	40	70	110	nS

NOTE:

UHF input sensitivity as measured in test fixture shown in Figure 2. Devices may overload if the input signal exceeds the maximum level specified.

* Overload levels are very layout sensitive and will probably require correlation in customer circuits. Overload levels of 500 mVRMS can easily be attained with various layouts.

BOTTOM

TEST FIXTURE CONSIDERATIONS

Pictured above is our standard MC12071 test fixture. High-frequency construction and design techniques are a must if the operation of the test fixture is to be stable and repeatable. Listed below are some considerations which must be observed to insure proper operation of the test circuit.

- Use a good ground plane with frequent ground connections.
- Use best available high-frequency type socket.
- Maintain a 50Ω environment on inputs except where it is necessary for the signal to pass through a component.

- Use best available high-frequency components and keep lead length to an absolute minimum. (Chip type ceramic capacitors are preferable.)
- Pin bypasses should be placed as close to the device as possible.

Note: Even after implementing the above fixture design and construction techniques some minimal correlation differences may exist due to inherent high-frequency characteristics variations.

MC12073

÷ 64 LOW-POWER PRESCALER

The MC12073 is a new member of Motorola's PLL family. It is a high-speed, low-power prescaler which divides by 64. The MC12073 can be used in all frequency synthesis applications. Typical applications include electronically tuned TV/CATV and communication systems as well as instrumentation.

An internal preamplifier is included in the MC12073. This preamplifier isolates the differential inputs and provides gain for the input signal. The MC12073 is pin compatible with Plessey's SP4632 and has ECL differential outputs.

- 1.1 GHz Toggle Frequency
- Low-Power: 23 mA Typical @ $V_{CC} = 5.0$ V
- High Input Sensitivity, 20 mV_{rms} @ $V_{CC} = 5.0 \pm 10\%$, $T_A = 0^\circ$ to $+70^\circ$ C
- 800 mV Minimum Peak-Peak Output Swing
- ECL Outputs

MAXIMUM RATINGS

Characteristic	Symbol	Range	Unit
Power Supply Voltage	V_{CC}	7.0	Vdc
Operating Temperature Range	T_A	0 to $+70$	$^\circ$ C
Storage Temperature Range	T_{stg}	-65 to $+175$	$^\circ$ C

MC12090

Advance Information

UHF PRESCALER

The MC12090 is a high-speed D master-slave flip-flop capable of toggle rates of over 700 MHz. It was designed primarily for high-speed prescaling applications in communications and instrumentation. This device employs two data inputs, two clock inputs as well as complementary Q and \bar{Q} outputs. There are no SET or RESET inputs.

THE "BETTER" PROGRAM

The "BETTER" program is offered on logic only, in dual-in-line ceramic and plastic packages.

Better Processing — Standard Product Plus:

LEVEL II (Suffix D)

- 100% burn-in to MIL-STD-883 test conditions — 160 hours at +125°C or 1.0 eV Arrhenius time/temperature equivalent.
- 100% post burn-in functional and dc parametric tests at 25°C (or max rated T_A at Motorola's option). Maximum PDA of 2% (functional) and 5% (DC and functional).

HOW TO ORDER

<u>MC10101</u>	<u>P</u>	<u>D</u>
Part Identification	Standard Package Suffix	BETTER PROCESSING LEVEL II = SUFFIX D

Part Marking

The Standard Motorola part number with the corresponding "BETTER" suffix can be ordered from your local authorized Motorola distributor or Motorola sales offices. "BETTER" pricing will be quoted as an adder to standard commercial product price.

"RAP" Reliability Audit Program for Logic Integrated Circuits

1.0 INTRODUCTION

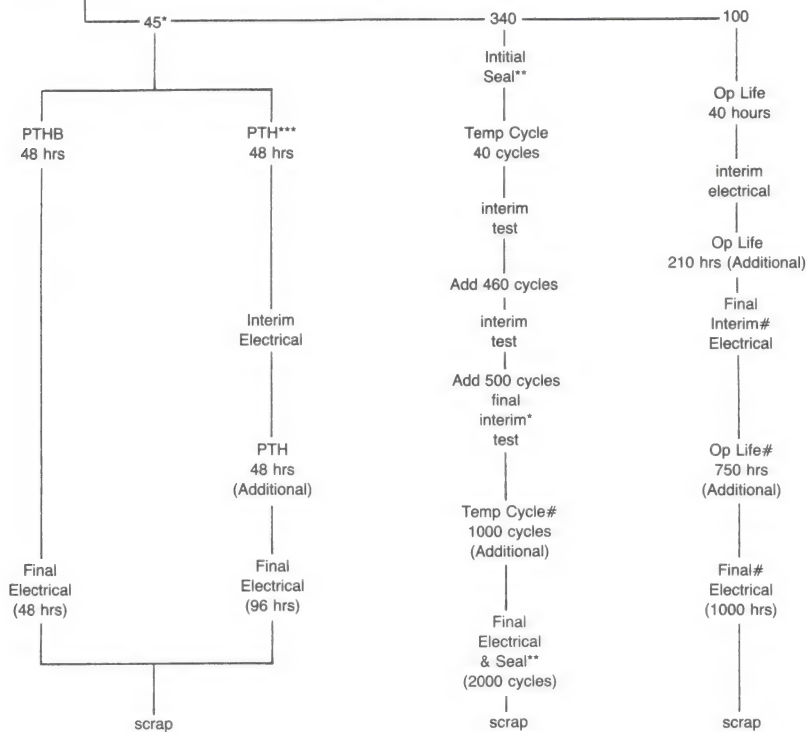

The Reliability Audit Program developed in March 1977 is the Motorola internal reliability audit which is designed to assess outgoing product performance under accelerated stress conditions. Logic Reliability Engineering has overall responsibility for RAP, including updating its requirements, interpreting its results, administration at offshore locations, and monthly reporting of results. These reports are available at all sales offices. Also available is the "Reliability and Qual-

ity Handbook" which contains data for all Motorola Semiconductors (#BR518S).

RAP is a system of environmental and electrical tests performed periodically on randomly selected samples of standard products. Each sample receives the tests specified in section 2.0. Frequency of testing is specified per internal document 12MRM15301A.

2.0 RAP TEST FLOW

Pull 500* piece sample from lot following Group A acceptance.

#One sample per month for FAST, LS, 10H, 10K, MG CMOS, and HSL CMOS.

*PTHB or PTH not required for hermetic products: reduce total sample size to 450 pcs.

Additional sample reductions for high pin-count devices per TABLE II notes.

**Seal (Fine & Gross Leak) required only for hermetic products.

***PTH to be used when sockets for PTHB are not available.

3.0 TEST CONDITIONS AND COMMENTS

PTHB — 15 psig/121°C/100% RH at rated V_{CC} or V_{EE} — to be performed on plastic encapsulated devices only.

TEMP CYCLING — MIL-STD-883, Method 1010, Condition C, $-65^{\circ}\text{C}/+150^{\circ}\text{C}$.

OP LIFE — MIL-STD-883, Method 1005, Condition C (Power plus Reverse Bias), $T_A = 145^{\circ}\text{C}$.

NOTES:

1. All standard 25°C dc and functional parameters will be measured Go/No/Go at each readout.
2. Any indicated failure is first verified and then submitted to the Product Analysis Lab for detailed analysis.
3. Sampling to include all package types routinely.
4. Device types sampled will be by generic type within each digital I/C product family (MECL, TTL, etc.) and will include all assembly locations (Korea, Philippines, Malaysia, etc.).
5. 16 hrs. PTHB is equivalent to approximately 800 hours of $85^{\circ}\text{C}/85\%$ RH THB for $V_{CC} \leq 15\text{ V}$.
6. Only moisture related failures (like corrosion) are criteria for failure on PTHB test.
7. Special device specifications (48A's) for digital products will reference 12MRM15301A as source of generic data for any customer required monthly audit reports.
